1994 KANSAS ALFALFA PERFORMANCE TESTS

INTRODUCTION

TEST OBJECTIVES AND PROCEDURES

An official performance testing program was established in 1980 by the Kansas Agricultural Experiment Station to provide Kansas growers with unbiased performance comparisons on many alfalfa varieties. Private companies enter varieties voluntarily at locations of their choice and pay fees to cover part of the costs of conducting the tests. Most tests are planted in mid-August or September; however, the Labette County test in Southeast Kansas usually is planted in the spring. Individual tests are conducted for a minimum of 3 or 4 years, then new tests are established. Announcements and entry forms are mailed to private companies in June for establishment of fall-seeded tests.

Descriptive information is presented with the results for each test (Tables 1-7). This information, including soil type, establishment methods, fertilization, pest control, irrigation, harvest dates, and growing conditions unique to that location, can help explain test and/or variety performance.

FORAGE YIELDS were estimated by harvesting four replications of each variety with a plot harvester. The amount of forage produced from a specific area ($35\text{-}80 \text{ ft}^2$) was weighed, and a subsample was taken to determine moisture content. This information was used to convert the plot weights to tons of dry matter per acre for each cutting, the season total, and the total for each previous season as presented in Tables 1-7. The forage yield over the lifetime of a particular test is presented as the total tons of dry matter produced per acre, the total expressed at 15% moisture, and a percentage of the test average.

At the bottom of each column, the Least Significant Difference (LSD) is listed at the 0.05 and 0.20 levels. Differences between varieties that are equal to or greater than the 0.05 LSD have a 1 in 20 chance of not being real. Differences equal to or greater than the 0.20 LSD have a 1 in 5 chance of not being real.

The Coefficient of Variability (C.V.) provides an estimate of the consistency of the results of a particular test. In these tests, C.V.'s below 10% generally indicate reliable, uniform data, whereas C.V.'s of 10-15% are not uncommon and generally indicate that the data are acceptable for rough comparisons. Tests with C.V.'s over 15% may still be useful, but variety comparisons lack precision.

1994 STATEWIDE GROWING CONDITIONS

Development of the 1994 alfalfa crop, as measured by the percent of alfalfa acreage harvested at any point in time, was typically 10 to 30 percent ahead of average and 20 to 40 percent ahead of 1993. This likely resulted from a combination of generally warmer temperatures and lower rainfall in 1994 compared to 1993. The season started with fairly good soil moisture status across the state. As the season progressed, topsoil moisture fluctuated with rainfall, and subsoil moisture was gradually depleted. Relatively dry periods in June and again in August caused nonirrigated alfalfa to depend on subsoil moisture reserves. (Statewide conditions from **Crop-Weather** reports, Kansas Agricultural Statistics, Topeka).

Severe insect damage to alfalfa was limited to localized infestations in 1994. March field surveys showed that a relatively high number

of adult alfalfa weevils had survived the winter, setting the stage for severe problems later. Fortunately, cool temperatures, beneficial insects, and a weevil-killing fungus apparently limited weevil populations in many fields. Treatment for weevils was not uncommon but was not as widespread as anticipated. Entomologists noted blue alfalfa aphids and pea aphids in many fields early in the season, but aphid populations seldom reached treatment levels. Potato leafhoppers caused severe yellowing in many northeastern fields in late June and July. Various types of blister beetles began to show up in July and were found for the remainder of the season. Grasshoppers occasionally caused appreciable damage to both established and new alfalfa stands later in the season. Various caterpillars (alfalfa caterpillar, garden webworm, green cloverworm, fall armyworm, forage loopers) threatened new seedlings in late August and September. (Insect information from **Cooperative Insect Survey Reports**, Kansas State Board of Agriculture).

Plant pathologists noted the presence of spring black stem in nearly all alfalfa fields they visited early in the season in central and eastern Kansas. In some cases, most of the lower leaves had been lost, and the disease threatened the upper canopy. Little other disease presence was noted for the remainder of the season. (Disease information from **Plant Disease Survey Reports**, Kansas State Board of Agriculture).

Over 3.1 million tons of alfalfa hay were harvested from 800,000 acres of alfalfa in Kansas in 1994. Production was down slightly from 1993, when over 3.2 million tons were harvested from 850,000 acres. The average yield increased from 3.8 tons per acre in 1993 to 3.9 tons per acre in 1994. (From January 12, 1995, **Crops** report; Kansas Agricultural Statistics, Topeka).

The 1994 alfalfa performance test results include data from two new tests: Riley

County dryland, planted in the spring of 1994 (Table 1) and Finney County irrigated, planted in the fall of 1993 (Table 7). The Brown County test was discontinued after a significant loss of stand during the 1993 season. Individual test information is presented with the results from each location

VARIETY CHARACTERIZATION

For variety selection, producers should consider the performance of a variety in each of the current tests where it appears, its performance over time and locations relative to familiar or check varieties, and the disease and insect resistance characteristics that are potentially important in their situation. Tables 1 through 7 contain updated yield data from individual tests currently in progress. Table 8 contains information for all currently marketed varieties that have been included in the Kansas Alfalfa Performance Tests. Fall dormancy, disease resistance, and insect resistance ratings were provided by developers of each variety and were reviewed by the Association of Official Seed Certifying Agencies (AOSCA), National Alfalfa Variety Review Board (NAVRB). The Certified Alfalfa Seed Council uses that information to publish its annual Fall Dormancy & Pest Resistance Ratings for Alfalfa Varieties, which was used as the source of the information in Table 8.

Fall dormancy values are based on the fall canopy height measured in Minnesota. Dormancy values often are related to the speed of regrowth, with the rapid regrowth types having higher values. The slower regrowth types have lower fall dormancy values.

ACKNOWLEDGMENTS

Cooperation of Research Center and Experiment Field personnel who provided land and performed many or all of the field operations is sincerely appreciated.

¹Leafhopper yellowing: 1 = very little or no yellowing evident, 5 = almost all leaves yellowed extensively.

LOCATION: Northeast Kansas Agronomy North Farm RILEY County Near Manhattan Smolan silt loam	1994 FERTILIZATION: 0-25-0	Correlation analysis revealed relatively strong, statistically significant relationships between yield and leafhopper yellowing ($r = -0.41$), between leafhopper yellowing and height ($r = -0.28$), and between height and yield ($r = 0.65$). Dry conditions in August limited late summer growth, which was allowed to accumulate for winter.
ESTABLISHMENT: March 17, 1994; RCBD, 4 reps Plots 3'x12'; 3'x12' harvested 15lb seed/a, Eptam for grass control. Seed planted as received from entrants.	1994 PEST CONTROL: None needed. 1994 CONDITIONS: The test was clipped on June 17 without measuring yields to remove uneven initial growth. Leafhoppers caused extensive yellowing and stunting in some varieties before the June 17 clipping and the July 28 harvest.

¹Information from **Alfalfa Varieties, 1994/95 Edition**, a publication of the Certified Alfalfa Seed Council, has been obtained from the Association of Official Seed Certifying Agencies (AOSCA), National Alfalfa Variety Review Board (NAVRB) Report. Blank spaces indicate variety is susceptible or has not been tested adequately. Codes and ratings are explained below. The variety information in these columns has not been verified, nor are any of the varieties endorsed, by the Certified Alfalfa Seed Council.TM

Fall dormancy ratings		Codes		Pest resistance ratings	
Check variety	Dormancy rating	FD=	Fall Dormancy	% Resistant plants	Resistance class
Norseman	1	Bw=	Bacterial Wilt	0-5%	Susceptible (S)
Vernal	2	Vw=	Verticillium Wilt	6-14%	Low Resistance (LR)
Ranger	3	Fw=	Fusarium Wilt	15-30%	Moderate Resistance (MR)
Saranac	4	An=	Anthracnose Race 1	31-50%	Resistance (R)
DuPuits	5	PRR=	Phytophthora Root Rot	>50%	High Resistance (HR)
Lahontan	6	SAA=	Spotted Alfalfa Aphid		
Mesilla	7	PA=	Pea Aphid		
Moapa 69	8	BAA=	Blue Alfalfa Aphid		
CUF 101	9	SN=	Stem Nematode		
		APH=	Aphanomyces Root Rot Race 1		
		SRK=	Southern Root Knot Nematode		
		NRK=	Northern Root Knot Nematode

Excerpts from the

UNIVERSITY RESEARCH POLICY AGREEMENT WITH COOPERATING SEED COMPANIES*

Permission is hereby given to Kansas State University to test our varieties and/or hybrids designated on the attached entry forms in the manner indicated on the test announcement. I understand that all results from Kansas crop performance tests belong to the University and to the public and shall be controlled by the University so as to produce the greatest benefit to the public. It is further agreed that the name of the University shall not be used by the company in any commercial advertising either in regard to this agreement or any other related matter.

* This agreement must be signed by an authorized individual before results involving the company's entries can be published by the Experiment Station. Except for the limitation that the name "KANSAS STATE UNIVERSITY" cannot be used in advertising (you may use something like "official state tests" or "state yield trials"), this does not preclude the use of data for advertising, if done in a fair manner.
