2016 KANSAS SOYBEAN PERFORMANCE TESTS

STATEWIDE GROWING CONDITIONS

The 2016 soybean season had an overall very favorable weather pattern. Early-season wet conditions delayed planting during the early side of the crop planting window. Early growth was slow as it was impacted by wet soil conditions. Delay of planting date could have caused yield reductions, primarily under typically high-yielding environments (>60 bushels per acre).

During the growing season, flooding was an issue in many locations, with Sedgwick and Brown counties being particularly hard hit. Early wet conditions, saturated soils, and inhibited root growth increased production issues related to root compaction and produced yellow leaves. Hail was also a problem across the state. There were 526 reports of large hail through October 15. Of those events, 223 were reported in May. Hail has a larger impact when it occurs later in the season, September to early October during grain filling. This is when the plant depends on the leaves, potentially affecting seed set (both seed number and weight).

As related to the precipitation conditions, all divisions averaged above normal for the period of April 1 through October 15. The greatest departure was in the south central, where the divisional average was 32.17 inches or 138% of normal. Unfortunately, the rains weren't evenly distributed across the region or across the season. At the St. John station, rainfall was below normal until mid-August. A wet end to August was followed by more normal conditions in September and October.

For soybean, temperatures weren't as much of a factor. The warmest readings were seen in mid-July, with the highest reading of 110°F reported on July 24 at Webster Dam. The latest freeze events recorded weren't particularly late with Quinter dropping to 24°F on April 15. The first autumn freezes were also close to average, with Sharon Springs dropping to 28°F on October 8, and Concordia reaching 29°F on October 13.

Luckily, the below-freezing temperatures did not greatly affect soybean since only small specific areas cultivated with soybean were affected (primarily Northcentral Kansas). Temperatures below 32 degrees, more absolute temperature than duration of the cold stress, will affect the crop. Necrosis of the leaf canopy is a visible symptom of freeze damage in soybeans. Early grain filling impact, timing of the freeze effect, will proportionally produce more yield

reduction (via seed set) than if the cold stress takes place close to the end of the season.

Reproductive temperature and precipitation conditions were favorable for grain filling process. Late-season rainy conditions delayed harvest, hindering the progress in some areas.

Despite the abovementioned challenges, in September the U.S. Department of Agriculture forecasted a soybean yield of 44 bushels per acre for the state of Kansas for the 2016 season, overpassing the 38.5 bushels per acre recorded for the 2015 growing season (Ignacio A. Ciampitti, Kansas State University Cropping Systems Specialist, and Mary Knapp, Kansas State University Climatologist).

TEST OBJECTIVES AND PROCEDURES

Soybean performance tests are conducted each year to provide information on the relative performance of new and established varieties and brands at several locations in Kansas.

Seeds for tests are from private seed companies, certified growers, and agricultural experiment stations (Table 1). Seed quality, including factors such as purity and germination, can be important in determining the performance of a variety. Soybean seed used for private and public entries in the Kansas Crop Performance Tests is prepared professionally and usually meets or exceeds Kansas Crop Improvement Certification standards. Relative performance of a given variety comparable to that obtained in these tests is best assured under similar environmental conditions and cultural practices and with the use of certified or professionally prepared seed. All companies known to be developing and marketing soybean varieties or brands are invited to submit test seed; interested companies enter on a voluntary, fee-entry basis.

Companies were invited to enter Glyphosate-resistant varieties in either the Glyphosate trials or in the conventional trials at Scandia, Ottawa, or Parsons.

Entries were planted in four-row plots with rows 30 inches apart and were replicated three or four times each. Seeding rate ranged from 7 to 12 seeds per foot of row. The center two rows of each plot were harvested for yield. Harvested row lengths ranged from 11 to 33 feet, depending on location. Cultural practices and rainfall for each test location are presented with each table. Results from this year's tests are presented in Tables 2 through 21. Relative yields of each entry from all locations are shown in

Tables 23 and 24. Test results also can be found online at: <http://www.agronomy.k-state.edu/services/crop-performance-tests/soybean>

DATA INTERPRETATION

Yields are recorded as bushels per acre (60 lb/bushel) adjusted to 13% moisture content, when moisture data are available. Seed yield also is expressed as a percentage of the test average to assist in identifying entries that consistently produce better than the average yield.

Maturity is the date on which 95% of the pods have ripened (browned). Delayed leaf drop and green stems are not considered when assigning maturity. About 1 week of good drying weather after maturing is needed before soybeans are ready to harvest.

Lodging is rated at maturity by the following scores:

1. Almost all plants erect
2. All plants slightly leaning or a few plants down
3. All plants leaning moderately (45%) or 25 to 50% of plants down
4. All plants leaning considerably or 50 to 80% plants down
5. Almost all plants down

Height is the average length from the soil surface to the top of the main stem of mature plants.

VARIETY OR BRAND SELECTION

Performance of soybean varieties or brands varies from year to year and from location to location, depending on factors such as weather, management practices, and variety adaptation. When selecting varieties or brands, producers should carefully analyze variety performance for two or more years across locations. Performance averaged over several environments will provide a better estimate of genetic potential and stability than performance based on a few environments.

Small differences in yield between any two varieties or brands usually are not important. Within maturity groups at each location, a LSD (least significant difference) was calculated. The significance level used to calculate the LSD was 10%. Unless two varieties differ in yield by more than the LSD, genetic yield potential of one entry cannot be considered superior to that of another.

The coefficient of variability (CV) represents an estimate of the precision in the replicated yield trials. A CV of less than 10% indicates a good test with a high level of reliability. CVs ranging from 10 to 15% are usually acceptable for performance comparisons. CVs greater than 15% generally lack sufficient precision to provide any more than a rough guide to cultivar performance. For tests in which the precision was insufficient to statistically compare performance among the entries, the LSD value has been replaced with the designation NS, indicating that seed yields were not significantly different.

North Central Kansas Experiment Field, Scandia, Republic County; Andrew Esser, agronomist

Good growing conditions and excellent weed control.

	April	May	June	July	Aug.	Sept.	Total
Rainfall:	4.0	8.2	1.0	6.2	6.7	2.2	30.2
Irrigation:				1.3	3.8	1.3	6.25

Planted 6/7/2016 at 167000 seeds/ac; harvested 10/24/2016; 26 ft. by 4-row plot; pesticides: Pre-emerge: Makaze (Glyphosate) 1 qt + Salvo (2,4-D) 1 pt. Post: Cobra 12.5 oz + 10oz Intensity One

Excerpts from the University Research Policy Agreement with Cooperating Seed Companies

Permission is hereby given to Kansas State University (KSU) to test varieties and/or hybrids designated on the attached entry forms in the manner indicated in the test announcements. I certify that seed submitted for testing is a true sample of the seed being offered for sale.

I understand that all results from Kansas Crop Performance Tests belong to the University and the public and shall be controlled by the University so as to produce the greatest benefit to the public. Performance data may be used in the following ways: 1) Tables may be reproduced in their entirety provided the source is referenced and data are not manipulated or reinterpreted; 2) Advertising statements by an individual company about the performance of its entries may be made as long as they are accurate statements about the data as published, with no reference to other companies' names or cultivars. In both cases, the following must be included with the reprint or ad citing the appropriate publication number and title: "See the official Kansas State University Agricultural Experiment Station and Cooperative Extension Service Report of Progress 1130, '2016 Kansas Performance Tests with Soybean Varieties,' or the Kansas Crop Performance Test website, www.agronomy.k-state.edu/services/crop-performance-tests/index.html, for details."
