CHAPTER I

INTRODUCTION

Modern industrial and agricultural products have been accompanied by many new waste by-products, which it is hoped, are reasonably utilized and should, at least, be sanitarily disposed of.

This investigation is concerned with water pollution which is caused by farm wastes — especially, farm animal waste. As Henderson (1) and Smith and Miner (2) pointed out, the stream pollution by rural land drainage from a watershed with farm animals, especially commercial cattle can be significant in terms of total demand on stream oxygen resources.

According to Miner and four members of ASAE (3), the quality parameters in cattle feedlot runoff are

(1) organic matter
(2) nitrogen compounds
(3) suspended solids
(4) bacterial populations and
(5) other chemicals.

These waste substances may be classified in three groups: organics, organisms and inorganics.

Smith and Miner (2) pointed out that runoff from a cattle feedlot pollutes the water by causing a lack of dissolved oxygen and/or high ammonia-nitrogen concentrations. When the oxygen content of the water becomes sufficiently decreased, fish, other aquatic animals, and plant life are killed. So, consideration has
to be given to the lack of dissolved oxygen in a waste water. Chemical oxygen demand (COD) which represents the chemical oxygen required to oxidize the organic material can be used as a quantitative measure for the organic matter in the waste water.

As mentioned by Sawyer (5), the COD test can be used as a means of measuring the pollutional strength of waste water because it is based upon the fact that all organic compounds, with a few exceptions, can be oxidized to carbon dioxide and water by the action of strong oxidizing agents under acid conditions. Generally, during the determination of COD, organic matter is converted to carbon dioxide and water regardless of the biological assimilability of the substances. As a result, COD values are greater than biochemical oxygen demand (BOD) values and may be much greater when significant amounts of biologically resistant organic matter are present. Cattle manure has a high content of lignin which is a biologically resistant organic. That is, as stated in Miner's thesis (4), COD is much greater than BOD in the analytical results of both cattle feedlot runoff and cattle manure. Besides, the COD test has the important advantage in the short time required for evaluation. This determination can be made in about three hours while a BOD test requires more than five days. Hence, COD is usually chosen rather than BOD as the index of the pollutional strength of the waste water. Here, COD is assumed to represent a hypothetical compound, so that COD concentration means the concentration of organic matter measured by its COD test.
The primary purpose of this research is to investigate the rate of transport, specifically that by molecular diffusion, of CCD through a porous stratum saturated by water such as the soil-manure surface in a feedlot. If the concentration of CCD in the water phase of the porous stratum is larger than that in the water on the surface of the feedlot, CCD will be transported to the surface waters by molecular diffusion. In order to predict the transfer rate of CCD by diffusion, the diffusion coefficient of CCD in water is needed. The secondary purpose of this research is to determine this diffusion coefficient experimentally.

In this study the artificial packed bed system shown in Figure 1 was employed to simulate the soil-manure system saturated by water. The system consisted of two parts, the packed bed saturated with solute-concentrated solution, and the well stirred solute-dilute solution. When the two solutions are brought into contact, solute is transferred from the packed bed to the well stirred solution because of the concentration difference. For this system, the analytical expressions were derived as a function of time for the upper well stirred solution and as function of time and position for the lower packed bed.

Before this system was used to measure the diffusion rate of CCD, it was tested by using a sucrose solution whose diffusivity was known. The transient diffusion with biochemical reaction in both parts of the system shown in Figure 1 was also considered mathematically.

It is obvious that without a system of reducing organic matter to a form in which its elements may be used again, almost
Fig. 1 Packed bed for simulation of a stratum (sideview).
all life would shortly cease on this earth. Micro-organisms with systems of extracellular and intracellular catalysts or enzyme function in the scheme of life to reduce these materials, extract energy from them and build new protoplasm. The biological reduction of these organic materials (waste) is dependent upon the synthesis of new bacterial protoplasm from them (6).

Usually, there are a number of diverse free-living forms of micro-organisms in animal waste. Each of these reduces a different kind of organic material in its proper environment. This overall reduction can be considered as an approximate first order irreversible chemical reaction.

For this case, the analytical expressions were derived as a function of time for the upper well stirred solution and as a function of time and position for the lower packed bed. When the value of diffusivity is known, the chemical reaction constant can be determined by forcing the experimental data to fit the mathematical expression.
CHAPTER II

DEVELOPMENT OF THE MATHEMATICAL MODEL OF THE SYSTEM

In this chapter, the system equations which characterize the diffusion process taking place in the system and the corresponding initial and boundary conditions will be derived. For this purpose, the system under consideration (Figure 1) is assumed to contain a binary liquid mixture. Actually, a solution of manure in water is a very complex liquid mixture.

The packed bed has a porosity $P$, cross-sectional area $A$, and tortuosity $T$. The packed bed is assumed to be saturated with a binary solution and to have a uniform initial concentration $c_i$, based on the void space. The solution in the upper reservoir has a volume $V$ and initial concentration $c_{1i}$.

If the density of this binary solution increases with its concentration, the initial concentration of the solution within the packed bed should be higher than that of the upper reservoir solution, so that no bulk flow will occur.

Mass transfer occurs because of the concentration difference between the upper solution and the solution within the packed bed. If there is no bulk flow, mass transfer is due to only molecular diffusion.

The following assumptions are made:

(1) The porous packed bed is a homogeneous solution layer.

(2) Solid particles are inert so that there is no mass transfer between the particles and the solution.

(3) The upper solution is a completely mixed solution such
that the concentration is always uniform in the reservoir.

(A) The diffusion coefficient is constant.

The problem can be considered as a one-dimensional diffusion profile with or without chemical reaction for one component. Also, two different systems are considered here, the one with finite thickness of the bed and the other with infinite thickness of the bed. All together four different cases are considered. These are

**CASE (I)**: Diffusion with finite thickness of the packed bed and without reaction

**CASE (II)**: Diffusion with finite thickness of the packed bed and with an irreversible first order homogeneous reaction

**CASE (III)**: Diffusion with infinite thickness of the packed bed and without reaction

**CASE (IV)**: Diffusion with infinite thickness of the packed bed and with an irreversible first order homogeneous reaction.

Diffusion equations and initial and boundary conditions will be derived for these four cases.

**CASE (I)**: Diffusion with finite thickness of the packed bed and without reaction

This system is assumed to have thickness \( L \). The diffusion of a substance through an elemental volume arbitrarily located within the packed bed is considered. By making a shell balance as
In Fick's second law of diffusion, called Fick's second law of diffusion, can be obtained [see Appendix A]:

\[
\frac{\partial c}{\partial t} = D_e \frac{\partial^2 c}{\partial z^2} \tag{1}
\]

The effective diffusion coefficient, \(D_e\), in equation (1) can be related with the molecular diffusivity, \(D_o\), as follows [see Appendix A]:

\[
D_e = \frac{D_o}{\tau} \tag{2}
\]

If a material balance is made at the interface of two layers, the following equation can be obtained [see Appendix A]:

\[
V \frac{dc_1}{dt} = D_e \frac{dc}{\partial z}\bigg|_{z=0} \quad \text{PA} \quad \text{for } t > 0 \tag{3}
\]

For this system the following initial and boundary conditions can be established:

(1) The concentrations within the packed bed and in the upper reservoir are initially \(c_1\) and \(c_{11}\) respectively, that is, when \(t = 0\),

\[
c = c_1
\]

and

\[
c_1 = c_{11}.
\]

(2) At the interface between two layers, the concentrations of both layers are the same, that is, at \(z = 0\),

\[
c = c_1 \quad \text{for } t > 0.
\]

(3) There is no mass transfer at the bottom of the bed, that
Here, equations (1) and (3) are to be solved for \( c \) and \( c_1 \) with the three initial and boundary conditions described above. The analytical solutions are given in terms of dimensionless concentrations \( \eta \) and \( \psi \) in Chapter III.

**CASE (II)**: Diffusion with finite thickness of the packed bed and with an irreversible first order homogeneous reaction.

This case can be treated in the same manner as Case (I) with the addition of the reaction both in the completely mixed solution and within the packed bed layer. If an irreversible first order homogeneous reaction is assumed to occur, equations (1) and (3) become

\[
\frac{\partial c}{\partial t} = D_e \frac{\partial^2 c}{\partial z^2} - kc
\]

and

\[
V \frac{dc_1}{dt} = D_e \frac{\partial c}{\partial z} \bigg|_{z=0} \frac{F_k}{V} - Vkc_1 \quad \text{for } t > 0
\]

Initial and boundary conditions are

(1) when \( t = 0 \),

\[ c = c_1 \]

and

\[ c_1 = c_{11} \]

(2) at \( z = 0 \),

\[ c = c_1 \quad \text{for } t > 0, \]

and

(3) at \( z = L \),
\[ \frac{\partial c}{\partial z} = 0 \]

The analytical solutions for this problem are given in Chapter III.

**CASE (III) :** Diffusion with infinite thickness of the packed bed and without reaction

This case is identical to Case (I) except for one boundary condition. Therefore, for this system the following partial differential equations can be written,

\[ \frac{\partial c}{\partial t} = D_e \frac{\partial^2 c}{\partial z^2} \quad (6) \]

and

\[ \gamma \frac{\partial c_1}{\partial t} = D_e \left. \frac{\partial^2 c}{\partial z^2} \right|_{z=0} \quad \text{for } t > 0 \quad (7). \]

Since the thickness of the packed bed is assumed infinite, the initial and boundary conditions become

(1) when \( t = 0 \),

\[ c = c_1 \]

and

\[ c_1 = c_{11}. \]

(2) at \( z = 0 \),

\[ c = c_1 \quad \text{for } t > 0, \]

and

(3) at \( z = \infty \),

\[ c = c_1. \]

The analytical solutions for \( c \) and \( c_1 \) are also given in Chapter III.
CASE (III) : Diffusion with infinite thickness of the packed bed and with an irreversible first order homogeneous reaction.

If an irreversible first order homogeneous reaction is assumed for the solutions both in the well-stirred reservoir and within the packed bed, equations (6) and (7) in Case (III) become

$$\frac{dc}{dt} = D_e \frac{d^2c}{dz^2} - kc$$

and

$$V \frac{dc_3}{dt} = D_e \frac{dc}{dz} \bigg|_{z=0} PA - V \frac{dc_1}{dt} \text{ for } t > 0$$

Initial and boundary conditions for this case are,

(1) when $t = 0$,

$$c = c_1$$

and

$$c_1 = c_{11}$$

(2) at $z = 0$,

$$c = c_1 \text{ for } t > 0$$

and

(3) at $z = \infty$,

$$c = c_1 \exp(-kt)$$

or

$$\frac{dc}{dt} = -kc.$$

The analytical solutions are contained in Chapter III.
CHAPTER III

ANALYTICAL SOLUTIONS OF THE SYSTEM EQUATIONS

In the preceding chapter, the differential diffusion equations and initial and boundary conditions have been derived for four different cases. In this chapter, the analytical expressions will be derived for these cases.

For simplicity, two sets of dimensionless quantities are introduced. The first set is

\[
\begin{align*}
X &= \frac{c - c_{14}}{c_1 - c_{11}} \\
Y &= \frac{c_1 - c_{14}}{c_1 - c_{11}} \\
\alpha &= \frac{D_0 t}{L^2} \\
\lambda &= \frac{z}{L} \\
\sigma &= \frac{ALD}{V}
\end{align*}
\]

(10).

The second set is

\[
\begin{align*}
X &= \frac{c - c_{14}}{c_1 - c_{11}} \\
Y &= \frac{c_1 - c_{14}}{c_1 - c_{11}} \\
\alpha &= \frac{D_0 \lambda^2 a^2}{V^2} t \\
\lambda_1 &= \frac{\sigma}{V}
\end{align*}
\]

(10,a).
If the important of the various quantities are compared to
the same, the first set is simpler and more suitable than the
second for Cases (I) and (II). However, for Cases (III) and (IV),
the first set, equation (10), can not be applied, but the second,
equation (10.a), can be used. Equation (10.a) can also be applied
to Cases (I) and (II) if desired. In the following developments,
equation (10) is used for Cases (I) and (II), and equation (10.a)
is used for Cases (III) and (IV). In Appendix (F), equation (10.a)
is used to obtain the analytical solution for Case (II).

**CASE (I)**: Diffusion with finite thickness of the packed bed and
without reaction

Diffusion equations, equations (1) and (3) in the preceding
chapter, are repeated below:

\[
\frac{d^2 c}{dz^2} = D \frac{1}{e} \frac{dc}{dz} \tag{1}
\]

and

\[
y \frac{dc_1}{dt} = D \frac{1}{e} \frac{dc}{dz} \bigg|_{z=0} \quad \text{PA} \quad \text{for } t > 0 \tag{3}.
\]

The initial and boundary conditions are

(1) when \( t = 0 \),

\[
c = c_1
\]

and

\[
c_1 = c_{11}
\]

(2) at \( z = 0 \),

\[
c = c_1 \quad \text{for } t > 0.
\]
By substituting equation (10) into equations (1) and (3),

they become

\[ \frac{\partial Y}{\partial \lambda} = \frac{\partial^{2} Y}{\partial \lambda^{2}} \]  

(11),

and

\[ \frac{\partial Y}{\partial \theta} = \alpha \frac{\partial Y}{\partial \lambda} |_{\lambda=0} \text{ for } \theta > 0 \]  

(12).

Accordingly, the initial and boundary conditions become

(1) when \( \theta = 0 \),

\[ X = 1 \]

and

\[ Y = 0, \]

(2) at \( \lambda = 0 \),

\[ X = Y \text{ for } \theta > 0, \]

and

(3) at \( \lambda = 1 \),

\[ \frac{\partial X}{\partial \lambda} = 0. \]

The analytical solution for this problem is available in Crank (7). In his problem, the solute is diffused from the well stirred solution to a solid plane sheet with the corresponding initial and boundary conditions. However, the final solutions listed in the book are the same as those obtained here (Case I).
This is because the set of differential equations are to be solved with corresponding initial and boundary conditions except that the diffusion proceeds in an inverse direction. That is, by using the Laplace transformation technique, the analytical solutions which give both the concentration of the solution in the upper reservoir as a function of time and the concentration of the solution within the packed bed as a function of time and distance from the interface are obtained as follows:

\[ Y(\theta) = \frac{\alpha}{1+\alpha} - \sum_{n=1}^{\infty} \frac{2}{(1+\alpha, \frac{\alpha}{\alpha})} \exp(-\beta_n^2 \theta) \]  

(13)

and

\[ X(\gamma, \lambda) = \frac{\alpha}{1+\alpha} - \sum_{n=1}^{\infty} 2 \cos(\beta_n(1-\lambda)) \frac{2 \cos(\beta_n(1-\lambda))}{(1+\alpha, \frac{\alpha}{\alpha}) \cos\beta_n} \exp(-\beta_n^2 \theta) \]  

(14),

where \( \beta_n \) satisfies the equation

\[ \beta \cot \beta + \alpha = 0 \]  

(15).

In equation (14), it is shown that at \( \lambda = 0 \), \( X(0, \lambda) = Y(\theta) \), which satisfies boundary condition (2). Also, if \( X \) and \( Y \) are plotted against \( \theta \) for a given \( \alpha \), for example, \( \alpha = 1.77276 \), Figure 2 is obtained. The corresponding values of \( \beta \) are listed in Table 1. According to Figure 2, the concentration of the packed bed at different distances from the interface changes with respect to time, with different transient phenomena. That is, at a point near the interface, the concentration decreases quickly with respect to time and then increases to approach the final steady state value, while at a point near the bottom of the packed bed,
Fig. 2. Transient behavior of the concentrations $X$ & $Y$ (identical with $X$ at $\lambda = 0$) when $\alpha = 1.77276$.

</table>
The concentration decreases slowly with respect to time to approach the final value. Figure 3 shows the distributions of dimensionless concentrations through the packed bed at various values of the dimensionless time \( \theta \), when \( d = 1.77276 \). From Figure 3, it is seen that the initial concentrations within the packed bed and in the well stirred reservoir are unity and zero respectively. As time goes on, the two concentrations reach a common final value.

If equations (13) and (14) are rewritten so that dimensionless concentrations may be expressed as functions of dimensional time and length,

\[
Y(t) = \frac{1}{1 + \frac{V}{ALP}} - \sum_{n=1}^{\infty} \frac{2 \cos(\frac{n \pi}{L} \theta)}{2 \cos(\frac{n \pi}{L} \theta) + \frac{2D}{L^2} t} \]

and

\[
X(t,z) = \frac{1}{1 + \frac{V}{ALP}} - \sum_{n=1}^{\infty} \frac{2 \cos(\frac{n \pi}{L} (1 - \frac{z}{L})) \cos(\frac{n \pi}{L} \theta) \cos^n \theta}{\frac{ALP V^2}{V \frac{Alp}{V}} \cos^n \theta} \]

are obtained.

If dimensionless concentrations \( Y \) and \( X \) are plotted with respect to dimensional time, \( t \), for different values of effective diffusivity, \( D \), Figures 4 and 5 are obtained for specified values of \( L, P \), and \( V \) corresponding to \( d = 1.77276 \). Eigenvalues from Equation (15) for that value are listed in Table 1. It can be seen from Figures 4 and 5 that for large values of effective diffusivity, mass transfer occurs rapidly and the system reaches
Fig. 3. Concentration profiles through the finite packed bed when $\alpha = 1.77276$.

$$X = \frac{C - C_{II}}{C_{I} - C_{II}}, \quad Y = \frac{C_{II} - C_{III}}{C_{I} - C_{II}}$$
Fig. 4. Effect of the diffusivity on the concentration of the upper solution for specified values of $A$, $L$, $P$ & $V$. 
Fig. 5. Effect of the diffusivity on the concentration within the packed bed for the specified values of $A$, $L$, $P$, $V$, and $Z$. 
The final value is a short \( 1 + \). In the effective diffusivity of a substance has infinite value, the concentrations in both layers reach a uniform and identical final value, \( c/(1+c) \), immediately after the diffusion process starts. For example, for the system with infinite thickness of the packed bed, both parts of the system have unit value of concentration as soon as the layers contact. On the other hand, if the effective diffusivity of the substance is zero, no change takes place between the two layers and both concentrations remain at their initial values.

In Figures 6, 7 and 5, \( Y \) and \( X \) are expressed with respect to time, \( t \), for different values of porosity \( P \), packed bed length \( L \), and upper reservoir volume \( V \). In each figure, one of the parameters is varied while each of the others are held constant.

According to Figure 6, the concentration in the well stirred reservoir is higher for the system having a large value of porosity, than for the system having a small value of porosity. Also, at a fixed position within the packed bed, the concentration for the former system is higher than that for the latter.

Figure 7 shows that the system having a greater thickness of the packed bed has a higher final value than the system with a smaller thickness. Thus, the system having infinite thickness has the largest final value, unity.

The effect of the well stirred reservoir volume on the concentrations in the upper reservoir and within the packed bed is shown in Figure 8. For the case in which the upper reservoir has an infinite volume of solution, \( Y \) remains zero and \( X \) approaches zero as time passes.
Fig. 6. Effect of the porosity on the concentrations $X$ (at $Z = 5$ cm) and $Y$. 

\[

Thus, as shown in Figure 2, if the concentration profile within the packed bed is expressed with respect to the distance from the interface at a certain instant while diffusion is proceeding, it can be seen that $\frac{\partial c}{\partial z} = 0$, corresponding to $\frac{\partial c}{\partial z} = 0$ at $z = L$, which satisfies boundary condition (3).

So far, many equations and figures have been illustrated. However, it can be concluded that equation (16) and Figure 4 are the most useful for the purpose of determining the diffusivity of a substance.

For all cases described above, eigenvalues are listed in Table 1.

**Case (II):** Diffusion with finite thickness of the packed bed and with an irreversible first order homogeneous reaction

The partial differential diffusion equations for this case, equations (4) and (5), are repeated below:

\[
\frac{\partial c}{\partial t} = D_c \frac{\partial^2 c}{\partial z^2} - kc \quad (4)
\]

\[
\gamma \frac{\partial c}{\partial t} = D_c \frac{\partial c}{\partial z} \bigg|_{z=0} \quad FA - Vkc = 0 \quad \text{for } t > 0 \quad (5).
\]

Initial and boundary conditions are

(1) when $t = 0$,

\[
c = c_0 \quad (c_1)
\]

and \[c_0 = c_{11}'.\]
Fig. 9. Effect of the packed bed thickness on the concentration within the packed-bed at a specified time (t = 50 min.).
(2) $\alpha = c$,
\[ c = c_1 \text{ for } t > 0, \]
and

(3) at $z = L$,
\[ \frac{\partial n}{\partial z} = 0. \]

By introducing equation (10) into equations (4) and (5), along with the initial and boundary conditions, the following equations can be obtained:

\[ \frac{\partial Y}{\partial t} = \frac{\partial^2 Y}{\partial \lambda^2} - R(X + S) \tag{18} \]
\[ \frac{\partial Y}{\partial t} + R(Y + S) = \frac{\partial Y}{\partial \lambda} \bigg|_{\lambda=0}, \text{ for } t > 0 \tag{19} \]

with new initial and boundary conditions,

(1) when $\lambda = 0$,
\[ X = 1 \]

and
\[ Y = 0 \]

(2) at $\lambda = 0$,
\[ X = Y \text{ for } t > 0, \]

and

(3) at $\lambda = 1$,
\[ \frac{\partial Y}{\partial \lambda} = 0, \]

where $\gamma = \frac{L^2 k}{D_c}$.
This is a kind of problem in which a solute can diffuse through a porous body saturated by a solution, while simultaneously reacting chemically or biochemically, both within the porous body and the well-stirred solution. Crank (9), Barakauskis (10), and Wilson (11) have described several similar problems such as problems involving diffusion in which the diffusing substance becomes immobilized within the packed bed as diffusion proceeds, a chemical reaction in which the rate of reaction depends on the rate of supply of one of the reactants by diffusion, and others. To solve these types of problems, they used the proper coordinates (cartesian, cylindrical, or spherical) that were convenient for their systems. However, each of them has considered that the reaction takes place in only one part of the system, for example, only within the packed bed. This is not always the case. When microorganisms consume organic compounds in feedlot runoff, it is reasonable to consider that the utilization of organic matter takes place both in the upper well-stirred solution layer and within the packed bed layer.

Now equations (13) and (19) are solved subject to the given three initial and boundary conditions. To accomplish this, Laplace transforms of equations (18) and (19) are obtained as

\[
\frac{\alpha \beta T}{\gamma^2} - (s + \beta)X + 1 - \frac{P}{s} = 0
\]  

(20)
\[ (s + \alpha \bar{Y} + \frac{P}{s} = \alpha \frac{\bar{Y}'}{\bar{Y}'} \mid \lambda = 0 \]  
\[ (21) \]

respectively. Also, transformed initial and boundary conditions are

(i) at \( \lambda = 0 \),
\[ \bar{Y} = \bar{Y} \text{ for } \theta > 0 \]
and

(ii) at \( \lambda = 1 \),
\[ \frac{\partial \bar{Y}}{\partial \lambda} = 0. \]

Once \( \bar{Y} \) from equation (20) has been obtained as a function of \( s \) and \( \lambda \), \( \bar{Y} \) can be obtained as a function of \( s \) as shown below [see Appendix B]:

\[ \bar{Y} = \left[ \frac{s - P \lambda}{s(s + 1)} \right] \left[ \exp((2 - \lambda)\sqrt{s+1}) + \exp(\lambda\sqrt{s+1}) \right] 
\[ \frac{1 + \exp(2/s+1)}{1 + \exp(2/s+1)} \]

\[ + \frac{s - P \lambda}{s(s + 1)} \]  

\[ (22) \]

\[ \bar{Y} = \frac{\alpha (\exp(2/s+1) - 1)}{(s + 2)[\sqrt{s+1}(\exp(2/s+1) + 1) + \alpha (\exp(2/s+1) - 1) + \frac{P \lambda}{s(s + 1)}} \]  

\[ (23) \]

Since,
\[ \exp(2/s+1) - 1 = 2 \exp(\sqrt{s+1}) \sinh(\sqrt{s+1}) \]  
\[ (24) \]
and
\[ \exp(2/s+1) + 1 = 2 \exp(\sqrt{s+1}) \cosh(\sqrt{s+1}) \]  
\[ (25) \].
Equation (23) becomes

\[ \Pi = \frac{\sinh(\sqrt{s+\Pi})}{(s+\Pi)[\sqrt{s+\Pi} \cosh(\sqrt{s+\Pi}) + \sinh(\sqrt{s+\Pi})]} - \frac{R\Pi}{s(s+\Pi)} \] (26)

If equations (24), (25) and (26) are substituted into equation (22), then equation (27) is obtained.

\[ \Pi = \frac{1}{s+\Pi} - \frac{\sqrt{s+\Pi} \cosh(\sqrt{s+\Pi}(1-\lambda))}{(s+\Pi)[\sqrt{s+\Pi} \cosh(\sqrt{s+\Pi}) + \sinh(\sqrt{s+\Pi})]} \]
\[ = - \frac{R\Pi}{s(s+\Pi)} \] (27).

By using the residue theory, the inverse Laplace transforms of \( \Pi(s) \) and \( \Pi(s,\lambda) \), \( Y(0) \) and \( X(0,\lambda) \), are obtained as follows [see Appendix C]:

\[ Y(0) = \frac{a}{1+\alpha} \exp(-R\theta) - \sum_{n=1}^{\infty} \frac{2\exp(-\beta_n^2 R^2)}{(1+\alpha + \beta_n^2 \theta)} \exp(-\beta_n^2(1-\alpha)) \] (28)

\[ X(0,\lambda) = \frac{a}{1+\lambda} \exp(-R\theta) - \sum_{n=1}^{\infty} \frac{2 \cos(\beta_n(1-\lambda))}{(1+\alpha + \beta_n^2 \theta) \cos^2 \beta_n} \exp(-\beta_n^2(1-\alpha)) \] (29)

These are the desired solutions.

It is seen that if \( R = 0 \), equations (28) and (29) become identical respectively with equations (13) and (14), the analytical solutions for the system with finite thickness of the packed bed and without chemical reaction. Figure 10 shows in dimensionless
Fig. 10. Effect of the dimensionless reaction constant $R$ on the concentrations $X$ & $Y$ when $S=1.0$ & $\alpha=1.77276$. 
For the concentration within the packed bed and in the all stirred reservoir ( Mention with $x$ at $z = 0$) change with respect to time for different values of the reaction constant, $k$ ($R$ includes $k$) when $S = 1.0$ and $a = 1.77276$. When $a = 1.77276$, $\beta$'s are listed in Table 1. Because an irreversible first order reaction is applied in both layers, the concentration in the upper reservoir increases until the diffusion process grows weak and chemical kinetics become dominant. At a position near the bottom, the concentration always decreases.

Figure 11 shows the concentration change vs. time for various values of $\lambda$ and $S$ when $R$ and $a$ are specified; for example, $R = 1.0$ and $a = 1.77276$. According to Figure 11, if time goes on to approach infinity, no matter what position may be considered, the concentration approaches $-S$ asymptotically.

From equation (28), if $a$ and $S$ are specified, for instance, $a = 1.77276$ and $S = 1.0$, $Y$ has a different profile for each value of $R$ as $\theta$ varies. These profiles are shown in Figure 12. With experimental data and with equation (28) and Figure 12, the dimensionless reaction rate constant $R$ can be obtained by forcing the experimental data to fit the theoretical solution. Once $R$ has been obtained with known $D_c$, then the chemical reaction constant, $k$, can be calculated with ease.

CASE (III): Diffusion with infinite thickness of the packed bed and without reaction

From the preceding chapter, the differential equations (6) and (7) are repeated below:
Fig. 11. Effect of the dimensionless initial concentration $S$ on the concentrations $X$ & $Y$ when $R=1.0$ & $\alpha=1.77276$. 

$$\theta = \frac{D}{L^2}$$
Fig. 12. Effect of the dimensionless reaction constant $R$ on the upper reservoir's concentration when $S=1.0$ & $\alpha=1.77276$. 
\[
\frac{\partial^2 c}{\partial x^2} = D \frac{\partial^2 c}{\partial x^2} \quad (6)
\]

and

\[
\frac{\partial c}{\partial x} = D \frac{\partial c}{\partial x} \bigg|_{x=0} \quad \text{for } t > 0 \quad (7)
\]

with initial and boundary conditions

1. when \( t = 0 \),
   \[ c = c_i \]
   and
   \[ c_1 = c_{11} \]

2. at \( z = 0 \),
   \[ c = c_1 \quad \text{for } t > 0, \]

and

3. at \( z = \infty \),
   \[ c = c_i \].

For simplicity, the dimensionless group, equation (10.a), is introduced.

By substituting equation (10.a) into equations (6) and (7), the following equations are obtained.

\[
\frac{\partial^2 \chi}{\partial \lambda_1^2} = \frac{\partial^2 \chi}{\partial \lambda_1^2} \quad (31)
\]

\[
\frac{\partial \chi}{\partial \lambda_1} = \left. \frac{\partial \chi}{\partial \lambda_1} \right|_{\lambda_1=0} \quad (32)
\]

Using these dimensionless expressions, the initial and boundary conditions become

1. when \( \lambda_1 = 0 \),
\[ x = 1 \]

and

\[ y = 0, \]

(2) at \( \lambda_1 = 0, \)

\[ y = x \quad \text{for} \quad \theta_1 > 0, \]

and

(3) at \( \lambda_1 = \infty, \)

\[ x = 1. \]

In order to solve this boundary value problem, Laplace transformation of equations (31) and (32) and the above initial and boundary conditions is carried out. Then

\[ \frac{s\pi}{\lambda_1^2} - s\pi^2 + 1 = 0 \quad (33) \]

\[ \tilde{y} = 1 - e^{\lambda_1 s} \bigg|_{\lambda_1 = 0} \quad (34) \]

and transferred boundary conditions,

(1) at \( \lambda_1 = 0, \)

\[ \tilde{x} = \tilde{y} \]

and

(2) at \( \lambda_1 = \infty, \)

\[ \tilde{x} = \frac{1}{s}. \]

are obtained.

The general solution for equation (33) can be obtained with the above two boundary conditions and once \( \tilde{y} \) has been obtained as
According to the Table of Inverse Laplace Transformation (11), the inverse Laplace transform of $\bar{Y}(s)$, $Y(\theta_1)$, is found in the following form:

$$Y(\theta_1) = 1 - \exp(\theta_1) \text{erfc}(\sqrt{\theta_1})$$

By substituting equation (36) into equation (35) and by using the Table of Inverse Laplace Transformation (11), the inverse Laplace transform of $\bar{X}(s, \lambda_1)$, $X(\theta_1, \lambda_1)$, is obtained.

$$X(\theta_1, \lambda_1) = 1 - \exp(\theta_1 + \lambda_1) \text{erfc}(\sqrt{\theta_1 + \frac{\lambda_1}{2\sqrt{\theta_1}}})$$

In equations (37) and (38), $Y$ and $X$ can be plotted with respect to $\theta_1$ as shown in Figure 13, which can be compared with Figure 2. While the concentration at any point within the finite thickness of the packed bed approaches a final value, $c/(1 + \alpha)$, as shown in Figure 2, that within the packed bed having infinite thickness approaches unity as shown in Figure 13. This is because of the fact that when the system has infinite thickness, the system has an infinite amount of substance to be diffused to the upper well stirred solution, whose volume is finite, until it has a uniform saturated concentration.
Fig. 13. Transient behavior of the concentrations X & Y (identical with X at λ=0) in the semi-infinite packed bed system.
Figure 1b, the plots of \( V \) vs. \( \lambda \), show concentration profiles within the packed bed at different moments. The concentrations in the upper reservoir are shown by flat lines.

**Case (II)**: Diffusion with infinite thickness of the packed bed and with an irreversible first order homogeneous reaction

For this case,

\[
\frac{\partial c}{\partial t} = D_e \frac{\partial^2 c}{\partial z^2} - kc \quad (8)
\]

and

\[
V \left. \frac{\partial c}{\partial z} \right|_{z=0} = F_e \frac{\partial c}{\partial z} = V_k c_0 \quad \text{for } t > 0
\]

are repeated with initial and boundary conditions

1. When \( t = 0 \),
   \[ c = c_1 \]
   and
   \[ c_1 = c_{11} \]
2. At \( z = 0 \),
   \[ c = c_1 \quad \text{for } t > 0 \]
   and
3. At \( z = \infty \),
   \[ c = c_1 \exp(-kt) \]
   or
   \[ \frac{dc}{dt} = -kc. \]

By substituting dimensionless group, equation (10.a), into equations
Fig. 14. Concentration profiles through the semi-infinite packed-bed.

\[ \chi = \frac{\alpha z}{L}, \quad \frac{c_i - c_1}{c_i - c_{11}} = \chi, \quad \frac{c_i - c_{11}}{c - c_{11}} = \chi \]

\[ \theta_i = \infty, \quad \theta_i = 0 \]

\[ \theta_i = 0.01 \]

\[ \theta_i = 0 \]
(2) \( \frac{\partial^2 \chi}{\partial x^2} = \frac{\partial^2 \chi}{\partial z^2} + R \left( X + S \right) \) \hspace{1cm} (2)

\[
\frac{\partial Y}{\partial t_1} + R \left( Y + S \right) = \left. \frac{\partial Y}{\partial t_1} \right|_{\lambda_1=0} \hspace{1cm} (2)'
\]

are obtained where,

\[ R_1 = \frac{xV^2}{D_k r_2 \pi^2} \]

and

\[ S_1 = \frac{c_{11}}{c_1 - c_{11}} \]

If equation (10.a) is substituted into the initial and boundary conditions, then

(1) when \( \theta_1 = 0 \),
\[ X = 1 \]
and
\[ Y = 0 \]

(2) at \( \lambda_1 = 0 \),
\[ X = Y \] \hspace{1cm} for \( \theta_1 > 0 \),
and

(3) at \( \lambda_1 = \infty \),
\[ \frac{\partial Y}{\partial t_1} = -R_1 (X + S_1) \]

are obtained.

By using the Laplace transformation, the analytical solutions for \( Y \) and \( X \) can be obtained as follows [see Appendix E]:
\[ Y(e_1) = e^{-e_1} - e^{-e_1} (1 - e_1) \cos(e_1) \]

\[ - e_1 (1 - e^{-e_1}) \]

\[ (\text{eq. 1}), \]

\[ Y(e_1, \lambda_1) = e^{-e_1} - e^{-e_1} (1 - e_1) \cos(\sqrt{\frac{e_1 + \lambda_1}{2\theta}}) \]

\[ - \lambda_1 (1 - e^{-e_1}) \]

\[ (\text{eq. 2}). \]

If \( R_1 = 0 \), then equations (1) and (2) become identical with equations (37) and (38), the analytical solutions for the system with infinite thickness of the packed bed and without reaction. Figure 15 shows in dimensionless form how the concentrations within the packed bed and in the well stirred reservoir (equal to \( X \) at \( \lambda_1 = 0 \)) vary with respect to time at different positions within the packed bed for various values of the dimensionless reaction constant \( R_1 \) when \( S_1 = 1.0 \). If \( R_1 = 0 \), this figure becomes identical to Figure 13.

Figure 16 shows the concentration change vs. time for various values of \( \lambda_1 \) and \( S_1 \) when \( R_1 = 1.0 \). It is seen in Figure 16 that as time goes on to reach infinity regardless of the position, the concentration approaches \(-S_1\) asymptotically.
Fig. 15. Effect of the dimensionless reaction constant $R_i$ on the concentrations $X$ & $Y$ (identical with $X$ at $\chi_i=0$) when $S_i=1.0$. 
Fig. 16. Effect of the dimensionless initial concentration $S_i$ on the concentrations $X$ & $Y$ (identical with $X$ at $\lambda_i = 0$) when $R_i = 1.0$.

\[
\frac{y}{c_{i} - c_{ii}} = \frac{c_{i} - c_{ii}}{c - c_{ii}}
\]

\[
X = \frac{c_{i} - c_{ii}}{c - c_{ii}}
\]
CHAPTER IV

EXPERIMENT WITH AQUEOUS SUCROSE SOLUTION

For the purpose of testing and calibrating the experimental set-up shown in Figure 17, which simulates the system under consideration, diffusion experiments were carried out by using an aqueous sucrose solution for which the diffusivity was known. These experiments enabled us to verify the mathematical expressions obtained in the previous chapters, and more specifically enabled us to determine the ranges of experimental condition for which the system equations are valid.

EXPERIMENTAL EQUIPMENT

The apparatus used for conducting the diffusion experiments consisted of a packed bed and a well stirred reservoir as shown in Figure 17. For this system two lucite cylinders, 10.716 cm ID and 19.65 cm inside depth and 10.716 cm ID and 33.2 cm long, for the packed bed and the well stirred reservoir respectively, were prepared and connected together by flanges.

To keep the upper reservoir at a uniform concentration for a given time, it was agitated by a stirrer operated by a motor which was controlled from a variable autotransformer powerstat. To prevent up-down flow, the stirrer selected was of the multiple flat-blade turbine type instead of the propeller type.

To prevent up-down bulk flow and moving particles, two sheets of 250 mesh stainless steel screen were installed between the packed bed and the well stirred reservoir. As inert particles,
Fig. 17. Schematic diagram of the experimental set-up.
25 — 30 mesh glass beads and 65 — 80 mesh glass typers were used.

To analyse the sucrose sample solutions taken from the upper reservoir, a Bausch & Lomb refractometer was used for measuring their concentrations by referring to the refractive index of sucrose solution listed in the International Critical Tables (14).

**EXPERIMENTAL PROCEDURES**

In a typical experimental run, the packed bed was saturated with an aqueous sucrose solution and in contact with a well stirred solution in the upper reservoir. Because the density of sucrose solution increases with its concentration, the concentration of the upper well stirred solution should be lower than that of the solution within the packed bed. This prevented bulk flow across the screens by gravitational force.

In order to diminish the effect of the agitating motion on bulk flow across the screens, the speed of the agitating motor was set as low as possible within the range so that the upper solution was able to maintain a uniform concentration at any time while an experimental run was proceeding. The upper reservoir could be checked for uniformity of concentration. That is, sample solutions were caught at two positions, at 3.5 cm below the surface of the well stirred solution and at 3.5 cm above the upper screen.

In analysing the sample solutions by the Bausch & Lomb refractometer, only 1 — 2 ml of the upper reservoir’s solution was needed. To lessen the error from volume change of the upper
solution when a sample was taken, an equal amount of solution whose concentration was identical to the previous sample was poured back into the reservoir.

The Bausch & Lomb refractometer was calibrated as shown in Figure 18 and Table 2. From Table 2, the following relation between \( x \) and \( y \) can be obtained:

\[
y = 0.9899 \times - 0.01238 \quad (43)
\]

When sample solutions were taken and their concentrations measured, a temperature correction was necessary because the refractive index of the sucrose solution was sensitive to the temperature of the circulating water of the Bausch & Lomb refractometer. For this refractometer, a temperature correction table was made for the deviation from the standard temperature \( (20 \, ^\circ C) \) as shown in its manual (19). Once the concentration of a sample sucrose solution was measured by the refractometer, the real concentration of the solution could be calculated according to the calibration equation, equation (43). The molar concentration of the solution was obtained from the weight \% concentration by using the Table of Density of Aqueous Sucrose solution in the International Critical Tables (14).

Under these considerations, experiments were performed for four different conditions listed in Table 3. For each run, sample solutions were caught only from the well stirred reservoir.

**EXPERIMENTAL RESULTS AND DISCUSSIONS**

The experimental data obtained under the experimental

conditions given in Table 3, which are the concentrations of the sample solutions taken from the upper well stirred reservoir, are listed in Table 4 for Run (3), in Table G-4 for Run (5), in Table G-5 for Run (6), and in Table G-6 for Run (8). These data were corrected for temperature deviation.

One of the factors, which caused the rise of the initial concentration in the upper well stirred solution appeared to be the initial disturbance which might exist when the upper solution contacted the packed bed. In other words, even though it was small, there existed bulk flow across the screens when both solutions were brought in to contact. This bulk flow might give rise to radial and axial concentration gradients near the interface within the packed bed. The agitating motion which kept the upper reservoir at a uniform concentration also must have affected the packed bed by inducing the convective motion. The initial penetration (or disturbance) and the continuous convective motion of the fluid must affect the system in a very complex fashion. It is very difficult, if not impossible, to analyze these complex effects. Preliminary investigation indicated that a single correction factor, i.e., the depth correction factor which reduces the effective thickness of the packed bed and increases the volume and the initial concentration of the upper solution, might satisfactorily correct for those disturbances. The corrected thickness of the packed bed \( L_0 \) and the corrected volume and initial concentration of the upper solution, \( V_c \) and \( c_{\text{incl}} \), change according to this depth correction factor \( L_0 \).

In order to determine this factor, a one dimensional search

55
technique (Golden Section method) was applied so that the sum of
the square deviations might be minimized. That is, \( \mathbf{L}_0 \) was searched
to minimize

\[
E = \sum_{l=1}^{n} (Y_c - Y_e)^2
\]

(44)

where \( E \) = sum of the square deviations,
\( m \) = number of data,
\( Y_c \) = corrected theoretical value, and
\( Y_e \) = corrected experimental value.

In this case, \( Y_c \) was obtained by modifying equation (16) to the
form of the following equation.

\[
Y_c = \frac{1}{1 + \frac{V_c}{AL_0P}} - \sum_{n=1}^{\infty} \frac{2}{AL_0P} \exp\left(-\frac{\beta_n^2 D \mathbf{e}}{L_0^2} t\right)
\]

(45)

where

\[
L_c = L - \mathbf{L}_0
\]

\[
V_c = V + AL_0P.
\]

And \( \beta_n \) is one of the eigenvalues which satisfy the following
eigenfunctions. Since \( \alpha = 0.43196 \) for Runs (3) and (5), the
eigenfunction is

\[
\beta \cot\beta + 0.43196 = 0
\]

(46).

Similarly, since \( \alpha = 0.42334 \) for Runs (6) and (8), the eigen-
function is

\[
\beta \cot\beta + 0.42334 = 0
\]

(47).
Two sets of the first twenty eigenvalues which satisfy equations (46) and (47) are listed in Table 5. The effective diffusivity, $D_e$, is defined as [see equations (1) and (3)]

$$D_e = \frac{D_0}{T}$$

Here, $T$ was chosen to be $\sqrt{2}$ as suggested by Penman (17) and Carmam (18). The molecular diffusivity, $D_0$, of sucrose in aqueous solution was taken as $4.242 \times 10^{-6}$ cm$^2$/sec (14, 15, 16). Thus, the effective diffusivity of aqueous sucrose solution, $D_e$, was computed to be $3.0 \times 10^{-6}$ cm$^2$/sec.

For a known value of effective diffusivity, $Y_e$ is a function of depth correction factor $L_0$ and time $t$.

The corrected dimensionless experimental value of concentration, $Y_e$, is obtained from the equation

$$Y_e = \frac{c_{le} - c_{lc1}}{c_{1} - c_{lc1}}$$  \hspace{1cm} (48)

where

$c_{le} =$ experimental value of $c_1$

$c_{lc1} =$ corrected value of $c_{1i}$.

$c_{lc1}$ is given by

$$c_{lc1} = \frac{Vc_{1i} + AL_0Pc_{1i}}{V + AL_0P}$$  \hspace{1cm} (49)

Accordingly, $Y_e$ is a function of $L_0$ for a given value of $t$.

Hence, by substituting equations (45), (48) and (49) into equation (44), it can be shown that the sum of square deviations,

</tbody>
</table>
E, is a function of the depth correction factor $L_o$ for given values of $D_e$ and $t$. That is, equation (44) can be rewritten as

$$E(L_o) = \sum_1^m (Y_c(L_o) - Y_e(L_o))^2$$

(50).

As described above, the one dimensional Golden Section method was used to search the depth correction factor $L_o$ such that the sum of square errors $E$ might be minimized. The computer flow chart and program for this method are listed in Appendix (G).

To examine the accuracy of each experimental run, the standard deviation (23) is obtained by the equation

$$\sigma = \sqrt{\frac{E}{n}}$$

(51).

For Runs (3), (5) and (6), the depth correction factors were found to be 1.0037, 0.6958 and 3.4374 cm respectively as shown in Figure 19. The standard deviations for those cases were 3.678x10^{-3}, 3.006x10^{-3} and 1.363x10^{-3} respectively. According to Figure 19, the system having a packed bed composed of small inert particles had a low value of depth correction while the system having a packed bed composed of large inert particles had a greater value. This could have been because the former bed was more compact than the latter.

For each of these correction factors, the corrected experimental data are listed in Table 4 for Run (3), and in Tables G-4 and G-5 for Runs (5) and (6) respectively. The data from Runs (3), (5) and (6) are plotted in Figure 20.
Fig. 19. Determination of depth correction factors.
Fig. 20 Corrected theoretical & experimental concentrations $Y_c$ & $Y_a$ vs. $t$ for Runs (3), (5), & (6).

\[ \frac{y_c}{y_a} = \frac{c_i - c_o}{c_i - c_{10}} \]

$D_e = 5.0 \times 10^{-6} \text{ cm}^2/\text{sec}$

$D_e = 3.0 \times 10^{-6} \text{ cm}^2/\text{sec}$

$D_e = 1.0 \times 10^{-6} \text{ cm}^2/\text{sec}$

Run (3)

Run (5)

Run (6)
For the first period up to about 25 hours, the concentrations in the upper reservoir obtained by experiments were smaller than those obtained by the theoretical equation with an average value of effective diffusivity of sucrose solution (3x10^{-6} \, \text{cm}^2/\text{sec}). In other words, for the first 25 hours the diffusivity of the aqueous sucrose solution measured by experiment was less than the average value of the available data, while after this period it was greater than the average. This might possibly be explained as follows: Generally, the diffusivity of sucrose has not been considered constant but has been considered as a function of the concentration of the solution. According to International Critical Tables (14), Henrion (15) and Van Hook (16), the diffusivity of aqueous sucrose solution decreases as its concentration increases.

Initially the concentration of the packed bed was high and it became low as the diffusion process was proceeding. Thus, the effective diffusivity of the aqueous sucrose solution through the packed bed was initially small and became larger gradually, up to a certain value. As previously mentioned, a single correction factor in terms of the depth correction factor was employed to take into account the effects of disturbances due to such factors as the initial penetration and the continuous convective motion in the bed. This factor changed the relative sizes of the thickness of the bed and the upper reservoir's volume. Since the conditions in the system, or more specifically the concentration profile in the system, changed with respect to time, the use of the single correction factor could not correct uniformly for
those disturbances from the onset of the process to the end of the process. Since the correction factor was determined for the whole range of the process, this overall or average correction factor might overcorrect the data from the initial part of the process and undercorrect the data from the later part of the process.

However, the diffusivity obtained here was not out of the range of its known values. The measured diffusivities of aqueous sucrose solutions have been in the range of $1.5 - 7.0 \times 10^{-6}$ cm$^2$/sec at temperatures of less than 25°C (14, 15, 16). Accordingly, the effective diffusivities, which are the values of true diffusivities divided by the approximate tortuosity $\sqrt{2}$, were in the range of $1.0 - 5.0 \times 10^{-6}$ cm$^2$/sec.

As listed in Table 3, for Runs (3), (5) and (6), the RPM of the agitating motor was in the range of 75 - 80. To check if the upper solution had a uniform concentration, sample solutions were arbitrarily taken both at the position of 3.5 cm below the surface of the upper solution and at the position of 3.5 cm above the upper screen. The concentrations at each of the points divided by their average were plotted in Figure 21, which showed that with 75 - 80 RPM of the agitating motor, the upper solution had uniform concentration in the reservoir.

To find the effect of large RPM of the agitating motor, Run (8) was carried out. In this situation, the effect of agitation was so large that equation (45) could not be used without adding another correction factor. Assuming that the effect of the agitating motor increases the effective diffusivity, the modified
effective diffusivity, \( K \), defined below can be used in equation (45).

\[
K = D_e + \pi
\]  
(52)

where,

\[ D_e = \text{effective diffusivity of a substance (in this case, sucrose) in the solution} \]

\[ \pi = \text{effect of agitating motor expressed in diffusivity units.} \]

Then, the sum of square errors \( E \) should also be rewritten as follows:

\[
E = \sum_{1}^{m} (Y_c(K, L_o) - Y_e(L_o))^2
\]  
(53)

It was shown that this is a two dimensional search problem for \( K \) and \( L_o \). By using the Box method, the computer program of which is listed in Chen's thesis (24), \( K \) and \( L_o \) were obtained to be \( 9.428 \times 10^{-5} \text{ cm}^2/\text{sec} \) and \( 0.7657 \text{ cm} \) respectively as shown in Figure G-2 and Table G-3 in Appendix (G). The standard deviation was \( 3.634 \times 10^{-3} \). The data for Run (8) were shown in Figure 22.

CONCLUSIONS

An experimental set-up which simulates the diffusion process of COD through a porous stratum saturated by water was proposed. The experimental set-up was tested and characterized by the experiments with sucrose solution whose diffusivity was known.

One single correction factor was suggested in terms of the depth correction factor to take into account the effects of
Fig. 22. Effect of speed of agitating motor.

\[ X; \text{ for 750 RPM} \]
\[ \bigcirc, \bigtriangleup; \text{ for 75 to 80 RPM} \]

- \( K = 9.428 \times 10^{-5} \text{ cm}^2/\text{sec} \)
- \( D_e = 3.0 \times 10^{-6} \text{ cm}^2/\text{sec} \)
disturbances such as the initial penetration of the upper solution and the continuous convective motion in the bed. It was found to be 0.84975 cm. It was also found that the speed of the agitation motor should be maintained within a limit of 75 — 80 RPM.

It can be concluded that this experimental set-up can be used as one of the simplest and quickest methods to determine the diffusivity of a substance in water with reasonable accuracy.
CHAPTER V

TRANSPORT RATE OF COD BY DIFFUSION THROUGH A POROUS PACKED BED SATURATED BY WATER

The experiments with feedlot runoff were carried out by using the system which was tested and calibrated in the previous chapter. Feedlot runoff contains a complex mixture of many components. For simplicity, it was decided to consider it as a hypothetical binary mixture. One component of this hypothetical binary mixture is the dissolved organic matter which is measured by the COD test, and the other the remaining materials. As previously mentioned, since COD was assumed to use as a hypothetical compound, the diffusivity of COD in feedlot runoff then is the overall or average diffusivity of various types of organic matter in the feedlot runoff, which may be called "pseudo-molecular diffusivity". As mentioned in the previous chapters, the so-called effective diffusivity of a substance characterizes the diffusivity through the porous packed bed which includes the tortuosity effect. Then the effective pseudo-diffusivity $D_{pe}$ of COD in feedlot runoff through a porous medium can be related as follows: that is,

$$D_{pe} = \frac{D}{T}$$  \hspace{1cm} (54)

where

$D_p = \text{pseudo-diffusivity (or pseudo-molecular diffusivity) of COD which represents the overall molecular diffusivity of various types of organic matter, cm}^2/\text{sec}$
The effective pseudo-diffusivity of COD can be obtained by using the system described in the foregoing chapters.

The experimental condition was the same as that of Runs (3) and (5) in which sucrose solution was used; thus, the calibration made with use of sucrose solution remained valid for the experiments with feedlot runoff.

**EXPERIMENTAL**

(A) Equipment

The equipment which had been used in the previous experiments with sucrose solution was used again here except for the Bausch & Lomb refractometer. To determine the COD concentration, the standard method (20) was used. Reflux apparatus consisted of a 300 ml round-bottom flask (Corning No. 4320 or equal) with ground glass neck 24/40 and a Friedrichs condenser (Corning No. 2600 or equal). Reagents employed were standard potassium dichromate solution (0.250 N), concentrated sulfuric acid, standard ferrous ammonium sulfate solution (0.25 N) and ferroin indicator solution.

(B) Procedures

(1) Preparation of Cattle Manure Solution

To prepare the cattle manure solution for use in the experiments, cattle manure was taken from the cattle feedlot located in the northern part of the campus of Kansas State University. This
manure was saturated with a large amount of water for two or three days. During this period, it was agitated a few times. After settling two days, the upper solution was taken and filtered with a sheet of filter paper. The filtrate was filtered again to remove even small manure particles.

Before this manure solution was used as an original waste water, it was necessary to make sure that no micro-organisms existed to reduce the COD concentration by consuming organic matter. To do this, the original waste water was heated at the temperature range of 120 — 150 °C for 1.5 — 2 hours. A chemical also could have been used to kill the micro-organisms, but it is difficult to assure that it does not affect the COD of the solution after killing the micro-organisms. Moreover, unless oxygen is supplied to the waste water, the oxidation by micro-organisms can be neglected. In this preparation, a heating method like that used in daily milk production was introduced.

As references, the typical daily manure production of a 1000 pound steer on full feed and the analytical results of feedlot runoff which had been obtained by Miner (4) are listed in Tables 6 and 7.

(2) Standard Method for Determining COD

The method of determining COD was mentioned in Standard Methods for the Examination of Water and Wastewater (20). According to this method, 0.250 N of potassium dichromate solution and 0.25 N of ferrous ammonium sulfate solution are the oxidizing and reducing agents respectively. The reducing agent was standardized against the oxidizing agent as follows:
Table 6. Typical Daily Manure Production of a 1000 pound Steer on Full Feed (4).

* Note: D = Dry  
W = Wet
Normality = \frac{(\text{ml} \times 
abla \text{Cr}_2 \text{O}_7) (0.25)}{\text{ml} \text{Fe(}\text{NH}_4\text{)}_2\text{(SO}_4\text{)}_2} \quad (55).

Because the COD test is designed to measure the oxygen requirement by oxidation of the organic matter present in the sample, it is important that no organic matter from outside sources appears in the sample during the test. Therefore, it is recommended that a parallel blank sample is tested.

If standard reagents as mentioned above are used, the COD of a sample solution can be computed as follows:

\[
\text{COD (mg/l)} = \frac{(u - v)(w)(8000)}{\text{ml sample}} \quad (56)
\]

where
\[
\begin{align*}
u &= \text{ml Fe(}\text{NH}_4\text{)}_2\text{(SO}_4\text{)}_2 \text{ used for blank} \\
v &= \text{ml Fe(}\text{NH}_4\text{)}_2\text{(SO}_4\text{)}_2 \text{ used for sample} \\
w &= \text{normality Fe(}\text{NH}_4\text{)}_2\text{(SO}_4\text{)}_2.
\end{align*}
\]

Here, the correction for the chloride interference was neglected.

(3) Procedures

The experimental procedures were almost the same as those in the case of sucrose solution, which were described in the preceding chapter, except for the method of determining the COD concentration.

Water was used as an original upper solution and the cattle manure solution mentioned in the foregoing subsection was used as an original solution for saturating the lower packed bed.

Twenty five ml of the solution were needed to determine the COD concentration of the solution taken from the upper reservoir.
To reduce the error caused by decreasing the volume of the upper reservoir, the same amount of solution (25 ml) with a concentration equal to that of the previous sample was poured back into the reservoir.

Two experiments were carried out under the different initial conditions given in Table 8.

EXPERIMENTAL RESULTS AND DISCUSSIONS

The experimental data obtained are listed in Tables 9 and 10 for experimental Runs (11) and (12) respectively. The values of the effective pseudo-diffusivity of COD were determined by forcing the experimental data to fit the mathematical expression. The conventional least square criterion as given by equation (44) in the preceding chapter was used. For convenience, equation (44) is repeated below:

\[ E = \sum_{1}^{2} (Y_{c} - Y_{e})^2 \]  \hspace{0.5cm} (44)

where

\[ Y_{c} \] satisfies the modified equation (45)

\[ Y_{c} = \frac{1}{V_{c}} - \sum_{n=1}^{2} \frac{2}{AL_{c}^{2} V_{c}^{2}} \exp\left(-\frac{\beta_{n}^{2}D_{pe}t}{L_{c}^{2}}\right) \]  \hspace{0.5cm} (45a)

and \[ Y_{e} \] represents the dimensionless experimental data defined in equation (43). \[ Y_{c} \] is a function of the effective pseudo-diffusivity \[ D_{pe} \]. To compute \[ Y_{c} \]'s, the eigenvalues \[ \beta_{n} \]'s which satisfy equation (15) in Chapter III are needed. \[ \alpha = 0.40571 \]

</table>
for both experimental Runs (11) and (12), and therefore, for the both cases, equation (15) is

\[ \beta \cot \beta + 0.40571 = 0 \]  

(57). 

The first twenty eigenvalues which satisfy equation (57) are listed in Table 11. The experimental data \( Y_e \)'s are shown in Tables 9 and 10 for Runs (11) and (12) respectively. Equation (44) can be rewritten as

\[ E(D_{pe}) = \sum_{l=1}^{m} (Y_c(D_{pe}) - Y_e)^2 \]  

(58).

To find the effective pseudo-diffusivity of COD such that the sum of square errors might be minimized, a one-dimensional search technique (the Golden Section method) was used. The computer program is listed in Appendix (G), and the computational results are shown in Figure 23 which indicates that the values of \( D_{pe} \) for runs (11) and (12) are \( 4.22 \times 10^{-6} \) cm²/sec and \( 5.77 \times 10^{-6} \) cm²/sec, respectively. In those cases, the values of the standard deviation from equation (51) are found to be \( 3.133 \times 10^{-3} \) and \( 2.077 \times 10^{-3} \) respectively.

The difference between the two independent experimental results can be largely attributed to the fact that the samples used in the two experiments came from two different batches of the cattle manure. It should be noted that the result of calibration of the experimental set-up (with sucrose solution) in term of a single depth correction factor was used in recovering the diffusivity of COD, and no arbitrary and independent determination of this factor was made in the experiments with manure.

Fig. 23. Effective pseudo-diffusivity of COD.
solution. This might also give rise to the deviations of the results from two experiments. Of course, the other obvious sources of the error are the assumptions that the complex manure solution is a binary mixture and that the diffusivity is constant. Considering those factors, the agreement between the two sets of results can be said to be very remarkable.

To determine the average value of \( D_{pe} \), all data from both runs were reanalyzed jointly. This value was found to be 5.02x10^{-6} \text{ cm}^2/\text{sec} (see Figure 23). The standard deviation was 3.049x10^{-3}.

To estimate the maximum possible error from this average value of \( D_{pe} \), the following effects are considered: that is, temperature, concentration, and correction factor. To estimate the effects of temperature and concentration on the diffusivity of COD, it is assumed that the organic matter in cattle feedlot run-off is sucrose. For an aqueous sucrose solution, the effects of temperature and concentration on the diffusivity are roughly 1.6x10^{-7} \text{ cm}^2/\text{sec} °\text{C} and 3.5x10^{-7} \text{ cm}^2/\text{sec} \text{mole} (15). According to the experimental conditions listed in Table 8, the maximum possible temperature and concentration deviations are about 4 °C and 0.5 moles. Thus, the maximum possible errors due to temperature and concentration deviations are approximately 6.4x10^{-7} \text{ cm}^2/\text{sec} and 1.75x10^{-7} \text{ cm}^2/\text{sec} respectively.

To estimate the possible error due to the correction factor, the correction factor of 1.0037 cm obtained from a single run (Run (3)) was used for the determination of the effective pseudo-diffusivity by using all data instead of the average correction
factor ($0.84975 \text{ cm}$). It was found to be $3.59 \times 10^{-6} \text{ cm}^2/\text{sec}$.

This indicates that the possible error due to the correction factor is approximately $5.02 \times 10^{-6} - 3.59 \times 10^{-6} = 1.43 \times 10^{-6}$ $(\text{cm}^2/\text{sec})$ in the units of effective diffusivity.

The total maximum error can be summed to be $[(6.4 \times 10^{-7} + 1.75 \times 10^{-7})/\sqrt{2}] + 1.43 \times 10^{-6} = 2.01 \times 10^{-6}$ $\text{cm}^2/\text{sec}$ in the units of effective diffusivity. This corresponds to $40\%$ error from the average $D_{pe}$, $5.02 \times 10^{-6} \text{ cm}^2/\text{sec}$.

An approximate value of the diffusivity of COD can be roughly estimated as follows: Although the composition of cattle manure depends on their feed ration, it has been shown that its components are roughly $65 - 75\%$ carbohydrates ($15 - 20\%$ of crude fiber and $45 - 60\%$ of N-free extract), $15 - 20\%$ protein ($N \times 6.25$), $5 - 15\%$ ash, and $1 - 5\%$ extract ether (21). Thus, in the cattle manure solution, there are carbohydrates, protein, ash and ether. However, most organic materials are carbohydrates and ether is quite rare. According to the International Critical Tables (14) and Gosting (22), the approximate overall diffusivity of carbohydrates is about $6.0 \times 10^{-6} \text{ cm}^2/\text{sec}$ and that of protein is about $1.0 \times 10^{-7} \text{ cm}^2/\text{sec}$. Therefore, the so-called pseudo-molecular diffusivity of COD in feedlot runoff can be estimated to be about $5.5 \times 10^{-6} \text{ cm}^2/\text{sec}$. In the units of the effective pseudo-diffusivity, it is approximately $4.0 \times 10^{-6} \text{ cm}^2/\text{sec}$.

If the experimental and estimated values are compared to each other, the experimental value is slightly larger than the approximate value given above. This can be accounted for by the fact that the manure solutions used in the experiments were not
completely homogeneous even though they had been filtered twice. That is, it is supposed that there was a considerable amount of fine suspensions in the solutions which gave rise to an increase in the experimentally determined value. All experimental results are shown in Figure 24.

**CONCLUSIONS**

The effective pseudo-diffusivity of COD through a porous stratum (medium) saturated by water was obtained. The average value of the effective pseudo-diffusivity of COD was found to be approximately $5.02 \times 10^{-6}$ cm$^2$/sec at a temperature of $25 \pm 2$ °C. This corresponds to the pseudo-molecular diffusivity of COD in water of $7.10 \times 10^{-6}$ cm$^2$/sec.

Information generated in this study is pertinent to water pollution caused by feedlot runoff. Since the effective pseudo-diffusivity of COD through the porous stratum saturated by water is small, it can be said that organic matter which diffuses from the earth underneath the feedlot to the surface of the lot probably does not contribute appreciably to the pollution due to the feedlot runoff.

According to Miner (4), considerable quantities of suspended solids were washed from the feedlot during runoff in his experiments. The conditions of high COD concentration corresponded to the conditions of high concentration of solid suspension. It may be concluded that as far as COD is concerned, the main contribution to the pollution due to the feedlot runoff is the manure suspension moving along with the runoff water.

APPENDIX. A.

SHELL PASS BALANCE IN POROUS MEDIA.
A shell mass balance is made over an arbitrary differential bed element to establish the differential equation for the diffusional process taking place in the system of a binary fluid mixture of species B and W in a packed bed. The law of conservation of mass of species B is applied to a volume element of the packed bed AzA fixed in the system shown in Figure A-1, in which a binary mixture of B and W is placed. For this packed bed system, a shell mass balance can be made in two ways. In the first approach, the packed bed is assumed as a homogeneous liquid layer and a shell mass balance is obtained by using a modified molecular diffusion coefficient, the effective diffusion coefficient, in place of the molecular diffusion coefficient. In the second approach, the system is considered to be composed of two parts, the continuous solid phase and the continuous liquid phase which exist parallel in the vertical direction. Mass transfer occurs only in the continuous liquid phase by the molecular diffusion.

The final resulting diffusion equations from these two different approaches should be interrelated. This implies that there exists a relation between the effective diffusion coefficient and the molecular diffusion coefficient. Here, it is assumed that the porous packed bed is isotropic, i.e., the pore space is randomly distributed and in any cross-sectional area the fraction not occupied by solids is always the same.

**METHOD I**

In the first approach, the packed bed of the system shown in Figure A-1 is assumed as a homogeneous liquid layer. The
Fig. A-1. Schematic diagram of the experimental set-up comprised of a packed bed & a well stirred solution.
concentration of the homogeneous layer is defined as the moles of species B which exist in the void space of the packed bed divided by the total volume of the bed. A shell mass balance is made within the hypothetical homogeneous layer as follows:

\[
\begin{align*}
\text{molar accumulation rate of B} & \quad \frac{\partial c_B}{\partial t} (\Delta z \Delta A) \\
\text{the volume element of the bed} & \quad M_B |_{z+\Delta z} A \\
\text{input of B across the cross-sectional area} & \quad M_B |_{z} A \\
\text{output of B across the cross-sectional area}
\end{align*}
\]

When the entire mass balance is written and divided through by \( \Delta z \Delta A \),

\[
\frac{\partial c_B}{\partial t} = \frac{\partial M_B}{\partial z}
\]  \hspace{1cm} (A-1)

is obtained by letting the size of the distance element decrease to zero. In this case, the molar flux of species B, \( M_B \), is expressed by using an effective diffusion coefficient \( D_e \) in place of the molecular diffusion coefficient \( D_o \). The molar flux is written as

\[
M_B = D_e \frac{\partial c_B}{\partial z}
\]  \hspace{1cm} (A-2)

By substituting equation (A-2) into equation (A-1)

\[
\frac{\partial c_B}{\partial t} = D_e \frac{\partial^2 c_B}{\partial z^2}
\]  \hspace{1cm} (A-3)

is obtained.

Another shell mass balance is made at the interface of the
upper solution and the hypothetical homogeneous liquid layer as follows:

- Molar accumulation rate of B in the volume of upper layer: \[ \frac{dc_1}{dt} V_1 \]
- Input of B across the cross-sectional area: \[ N_B \bigg|_{z=0} A \]
- Output of B across the cross-sectional area: 0.

When the entire mass balance is written

\[ V_1 \frac{dc_1}{dt} = M_B \bigg|_{z=0} A \]  \hspace{1cm} (A-4)

or

\[ V_1 \frac{dc_1}{dt} = D \frac{\partial c_b}{\partial z} \bigg|_{z=0} A \]  \hspace{1cm} (A-5)

is obtained.

The initial and boundary conditions can also be established as follows:

1. The concentrations within the hypothetical homogeneous layer and the upper reservoir are initially \( c_{b1} \) and \( c_{l1} \) throughout; that is, when \( t = 0 \),
   \[ c_b = c_{b1} \]
   \[ c_l = c_{l1} \]
2. At the interface of the two layers, the concentrations of both layers have the relationship; that is, at \( z = 0 \),
   \[ c_b = Fc_l \] for \( t > 0 \).
3. There is no mass transfer at the bottom of the lower layer; that is, at \( z = L \)
   \[ \frac{dc_b}{dz} = 0. \]
Nomenclature

\( A \) = total cross-sectional area, \( \text{cm}^2 \)

\( c_b = \) bulk concentration of species B within the hypothetical homogeneous layer, that is, the moles of species B within the void space of the bed divided by the total volume, \( \text{g-moles/cm}^3 \)

\( c_1 \) = concentration of species B in the upper reservoir, \( \text{g-moles/cm}^3 \)

\( D_e \) = effective diffusion coefficient of species B, \( \text{cm}^2/\text{sec} \)

\( D_c \) = molecular diffusion coefficient of species B, \( \text{cm}^2/\text{sec} \)

\( N_B \) = molar flux of species B based on the bulk concentration of the homogeneous layer, \( \text{g-moles/cm}^3\text{sec} \)

\( P \) = porosity of the bed

\( t \) = time, sec

\( V_l \) = volume of the upper solution, \( \text{cm}^3 \)

\( z \) = distance from the interface of the two layers in the direction of the bottom, \( \text{cm} \)

METHOD II

The second approach visualizes the system as shown in Figure A-2. A shell mass balance is made within the lower bed of the system shown in Figure A-2 as follows:

\[
\frac{\partial c}{\partial t} (A_Z PA) \\
N_B |_{z+\Delta z} (PA)
\]

molar accumulation of B in volume element of the bed

input of B across the reduced area of cross-section available for molecular movements
Fig. A-2. Schematic diagram of the system equivalent to that shown in Fig. A-1.
output of $\mathcal{B}$ across the reduced area of cross-section available for molecular movements

If the entire mass balance is written and divided through by $\Delta z PA$,

$$\frac{d\mathcal{B}}{dt} = \frac{\Delta N_B}{\Delta z}$$ (A-6)

is obtained by letting the size of the distance element decrease to zero. Since there is no bulk flow in the system, the molar flux is written as

$$N_B = D_0 \frac{d\mathcal{B}}{dz}$$ (A-7).

According to Penman (17) and Carman (18), the rate of diffusion through a porous body is reduced due to the increased path length imposed by the tortuous nature of the channels which the molecular current must follow. Thus, the actual molar flux through the original packed is smaller than that through the system shown in Figure A-2 by a factor of $\frac{1}{T}$. $T$ is the tortuosity of the bed — i.e., the ratio of the path length through the porous medium to the direct or "crow-flight" distance through the medium. The tortuosity is always larger than unity. The actual molar flux $(N_B)_a$ can be written as

$$(N_B)_a = \frac{N_B}{T}$$ (A-8)

and must be used in place of $N_B$ in equation (A-6). Equation (A-6) is rewritten as

$$\frac{d\mathcal{B}}{dt} = \frac{\Delta(N_B)_a}{\Delta z}$$
or
\[
\frac{\partial c}{\partial t} = \frac{1}{T} \frac{\partial \bar{c}_{l}}{\partial z}
\]
\[
= \frac{D_{c}}{T} \frac{\partial^{2} c}{\partial z^{2}}
\]
(A-9).

Also, if another shell mass balance is obtained at the interface of the two layers,
\[
V_{L} \frac{dc_{l}}{dt} = \frac{D_{c}}{T} \frac{\partial c}{\partial z} \Big|_{z=0} \quad \text{(PA)}
\]
(A-10)
is obtained.

The initial and boundary conditions are as follows:

(1) When \( t = 0 \),
\[
c = c_{1}
\]
\[
c_{1} = c_{11}.
\]
(2) At \( z = 0 \),
\[
c = c_{1} \quad \text{for} \ t > 0.
\]
(3) At \( z = L \),
\[
\frac{\partial c}{\partial z} = 0.
\]

**Nomenclature**

- \( A \) = total cross-sectional area of the bed, cm\(^{2}\)
- \( c \) = concentration of species B in the void space of the bed, that is, the actual concentration of the fluid within the void space of the bed, g-moles/cm\(^{3}\)
- \( c_{L} \) = concentration of species B in the upper reservoir, g-moles/cm\(^{3}\)
- \( D_{c} \) = molecular diffusion coefficient of species B, cm\(^{2}\)/sec
\((N_B)a = \text{actual molar flux of species } B \text{ through the porous medium, moles/cm}^2\text{sec}\)

\[ P = \text{porosity of the bed} \]

\[ t = \text{time, sec} \]

\[ T = \text{tortuosity of the bed} \]

\[ V_L = \text{volume of the upper solution, cm}^3 \]

\[ z = \text{distance from the interface of the two layers in the direction of the bottom, cm} \]

**COMPARISON OF THE TWO METHODS**

It can be seen that equation (A-3) corresponds to equation (A-9) and that equation (A-5) corresponds to equation (A-10).

In the four equations above, it is obvious that

\[ c_b = P \cdot c \]

\[ c_1 = c_L \]

and

\[ V_1 = V_L \]

Therefore, the relation between the effective diffusion coefficient \(D_e\) and the molecular diffusion coefficient \(D_o\) can be obtained as

\[ D_e = \frac{D_o}{T} \]  \hspace{1cm} (A-11)
APPENDIX. B.

DERIVATION OF EQUATIONS (22) AND (23) FROM EQUATIONS (20) AND (21) WITH BOUNDARY CONDITIONS.
Equations (20) and (21) are repeated below:

\[
\frac{d^2X}{d\lambda^2} - (s + R) X + 1 - \frac{RS}{s} = 0 \quad (20)
\]

\[
(s + R)X + \frac{RS}{s} = \alpha \left. \frac{dX}{d\lambda} \right|_{\lambda=0} \quad (21).
\]

Boundary conditions are

(i) at \( \lambda = 0 \), \( X = \bar{X} \) for \( \theta > 0 \) and

(ii) at \( \lambda = 1 \), \( \frac{dX}{d\lambda} = 0 \).

Equation (20) is a simple ordinary second order differential equation with two boundary conditions. The homogeneous solution, \( \bar{X}_h \), for equation (20) can be obtained as

\[
\bar{X}_h = a \exp(-\lambda\sqrt{s+R}) + b \exp(\lambda\sqrt{s+R}) \quad (B-1)
\]

where \( a \) and \( b \) are arbitrary constants to be determined.

\( F \) is assumed to be the particular solution, \( \bar{X}_p \), for equation (20); that is,

\[
\bar{X}_p = F \quad (B-2).
\]

Thus, the general solution of equation (20) is

\[
X = \bar{X}_h + \bar{X}_p = a \exp(-\lambda\sqrt{s+R}) + b \exp(\lambda\sqrt{s+R}) + F \quad (B-3).
\]

In order to evaluate \( F \), equation (B-3) is substituted into equation (20) and equation (B-4) is obtained as follows:

\[
\frac{d^2\bar{X}}{d\lambda^2} - (s + R)\bar{X} + 1 - \frac{RS}{s}
\]
\[
= (s + R) [a \exp(-\lambda \sqrt{s+R}) + b \exp(\lambda \sqrt{s+R})]
\]
\[- (s + R) [a \exp(-\lambda \sqrt{s+R}) + b \exp(\lambda \sqrt{s+R}) + F] + 1 - \frac{RS}{s} = 0
\]

or

\[
F = \frac{s - RS}{s(s + R)}
\]  \hspace{1cm} (B-4).

Substituting equation (B-4) into equation (B-3), equation (B-3) becomes

\[
\bar{X} = a \exp(-\lambda \sqrt{s+R}) + b \exp(\lambda \sqrt{s+R}) + \frac{s - RS}{s(s + R)}
\]  \hspace{1cm} (B-5).

Now the integral constants \(a\) and \(b\) must be determined with boundary conditions (i) and (ii). From boundary condition (i),

\[
Y = a + b + \frac{s - RS}{s(s + R)}
\]  \hspace{1cm} (B-6).

From boundary condition (ii),

\[
\frac{d\bar{X}}{dx} \bigg|_{\lambda=1} = \sqrt{s+R}[b \exp(\sqrt{s+R}) - a \exp(-\sqrt{s+R})] = 0
\]

or

\[
a = b \exp(2\sqrt{s+R})
\]  \hspace{1cm} (B-7).

If equations (B-6) and (B-7) are solved simultaneously with respect to \(a\) and \(b\), the following equations are obtained.

\[
a = \frac{\exp(2\sqrt{s+R})[\bar{Y} - \frac{s - RS}{s(s + R)}]}{1 + \exp(2\sqrt{s+R})}
\]  \hspace{1cm} (B-8)

and

\[
b = \frac{\frac{s - RS}{s(s + R)}}{1 + \exp(2\sqrt{s+R})}
\]  \hspace{1cm} (B-9).

Substituting equations (B-8) and (B-9) into equation (B-5),
it yields

\[ X = \frac{\nu - \frac{s - R\Sigma}{s(s + R)}}{1 + \exp(\frac{2}{s + R})} \exp(2 - \lambda)\sqrt{s + R} + \exp(\lambda\sqrt{s + R}) \]

\[ + \frac{s - R\Sigma}{s(s + R)} \]  

(22).

By substitution of equation (22) into equation (21), \( Y \) can be obtained as follows:

\[ Y = \frac{\alpha (\exp(2\sqrt{s + R}) - 1)}{(s + R)[\sqrt{s + R}(\exp(2\sqrt{s + R}) + 1) + \alpha (\exp(2\sqrt{s + R}) - 1)]} \]

\[ - \frac{RS}{s(s + R)} \]  

(23).
APPENDIX. C.

DERIVATION OF EQUATIONS (28) AND (29) FROM EQUATIONS (26) AND (27).
Equation (26) is repeated below:

\[
\overline{Y} = \frac{\alpha \sinh(\sqrt{s+R})}{(s + R)[\sqrt{s+R} \cosh(\sqrt{s+R}) + \alpha \sinh(\sqrt{s+R})]} - \frac{RS}{s(s + R)}
\]

\[= \overline{Y}_1 - \overline{Y}_2 \text{ (26)}\]

where

\[
\overline{Y}_1 = \frac{\alpha \sinh(\sqrt{s+R})}{(s + R)[\sqrt{s+R} \cosh(\sqrt{s+R}) + \alpha \sinh(\sqrt{s+R})]}
\]

and

\[
\overline{Y}_2 = \frac{RS}{s(s + R)} \text{ (C-1)}
\]

In order to obtain the inverse Laplace transforms of \(\overline{Y}_1\) and \(\overline{Y}_2\), the residue theory (12) can be used. According to the residue theory (12), the inverse transform of \(\overline{Y}\) is represented as the series of residue of \(\exp(s\theta)\) \(\overline{Y}_1\):

\[
Y(\theta) = \sum_{n=1}^{\infty} r_n(\theta) \text{ (C-3)}
\]

When a pole \(s_n\) is a simple pole, the residue can be written as

\[
r_n(\theta) = \lim_{s \to s_n} (s - s_n) \exp(s\theta) \overline{Y}(s)
\]

\[= \exp(s_n \theta) \lim_{s \to s_n} (s - s_n) \overline{Y}(s) \text{ (C-4)}.
\]

If, in a particular case, in which \(\overline{Y}(s)\) has a fractional form, such as

\[
\overline{Y}(s) = \frac{p(s)}{q(s)} \text{ (C-5)},
\]

where \(p(s)\) and \(q(s)\) are analytic at \(s = s_n\) and \(p(s_n) \neq 0\), then
the residue can be expressed as

\[ r_n(\theta) = \frac{p(s_n)}{q'(s_n)} \exp(s_n \theta) \]  

(C-6).

Therefore, equation (C-3) becomes

\[ Y(\theta) = \sum_{n=1}^{\infty} \frac{p(s_n)}{q'(s_n)} \exp(s_n \theta) \]  

(C-7).

First, the inverse form of \( Y_1 \) is obtained. Poles of equation (C-1) are where

\[ s + R = 0 \]  

(C-8).

\[ \sqrt{s+R} \cosh(\sqrt{s+R}) + \alpha \sinh(\sqrt{s+R}) = 0 \]  

(C-9).

It is obvious that the pole from equation (C-8) is simple, and that from equation (C-9) an infinite number of poles are obtained.

From equation (C-1),

\[ Y_1 = \frac{p_1(s)}{q_1(s)} = \frac{p_1(s)}{(s + R) Q_1(s)} \]  

(C-10)

where,

\[ p_1(s) = \alpha \sinh(\sqrt{s+R}) \]

\[ q_1(s) = (s + R) \sqrt{s+R} \cosh(\sqrt{s+R}) + \alpha \sinh(\sqrt{s+R}) \]

\[ Q_1(s) = \sqrt{s+R} \cosh(\sqrt{s+R}) + \alpha \sinh(\sqrt{s+R}). \]

From equation (C-3),

\[ s_n = -R \]  

(C-11).

Since \( p_1(-R) = 0 \), L'Hôpital's Rule must be used to obtain the
residue. Then,

\[ r(\theta) = \exp(-\Theta) \lim_{s \to -\infty} \frac{P_1(s)}{Q_1(s)} = \left(\frac{\alpha}{1 + \alpha}\right) \exp(-\Theta) \quad (C-12). \]

From equation (C-9), it can be shown that \( \sqrt{s+n} \) is a pure imaginary number; that is,

\[ \sqrt{s_n + R} = 1 \beta_n \]

or

\[ s_n = -(\beta_n^2 + R) \quad (C-13). \]

Thus, equation (C-9) can be rewritten as follows:

\[ \sqrt{s+n} \cosh(\sqrt{s+n}) + \alpha \sinh(\sqrt{s+n}) = 1 \beta \cos \beta + i \alpha \sin \beta = 0 \]

or

\[ \beta \cot \beta + \alpha = 0 \quad (C-14). \]

Now, an infinite number of \( \beta \), i.e., \( \beta_1, \beta_2, \ldots, \beta_n \ldots \), which satisfy equation (C-14) can be obtained. Accordingly, an infinite number of poles, i.e., \( s_1, s_2, \ldots, s_n \ldots \), which satisfy equation (C-9) can be calculated. By the residue theory,

\[ r_n(\theta) = \lim_{s \to s_n} \frac{P_1(s)}{Q_1(s)} \exp(\theta s) \]

\[ = \frac{\alpha \sinh(\sqrt{s_n + R}) \exp(s_n \theta)}{(s_n + R)[\frac{1}{2\sqrt{s_n + R}} \cosh(\sqrt{s_n + R}) + \frac{1}{2\sqrt{s_n + R}} \sinh(\sqrt{s_n + R}) + \frac{\alpha}{2\sqrt{s_n + R}} \cosh(\sqrt{s_n + R})]} \quad (C-15). \]

Since,

\[ \sinh(\sqrt{s_n + R}) = -\frac{\sqrt{s_n + R}}{\alpha} \cosh(\sqrt{s_n + R}) \]

and
Here, an infinite number of $r_n(\theta)$ are obtained.

From equations (C-12) and (C-16), the inverse transform of $Y_1(s)$, $Y_1(\theta)$, is produced as follows:

$$Y_1(\theta) = \left( \frac{\alpha}{1 + \alpha} \right) \exp(-R\theta) - \sum_{n=1}^{\infty} \frac{2 \exp(-(\beta_n^2 + R)\theta)}{(1 + \alpha + \frac{\beta_n^2}{\alpha})}$$

Next, the inverse form of $\overline{Y}_2$ is obtained. In equation (C-2), there exist two poles given in the following equations:

$$s = 0 \quad \text{(C-18)}$$
$$s + R = 0 \quad \text{(C-19)}$$

Similarly,

$$r_n(\theta) = \lim_{s \to 0} s \overline{Y}_2(s) = S$$

for $s = 0$, and

$$r_n(\theta) = \lim_{s \to -R} (s + R) \overline{Y}_2(s) \exp(s\theta)$$

$$= -S \exp(-R\theta)$$

for $s = -R$.

Therefore, from equations (C-20) and (C-21) the inverse transform of $Y_2(s)$, $Y_2(\theta)$, can be obtained as follows:
Finally, the inverse transform of $\bar{Y}(s)$, $Y(\theta)$, can be derived as follows:

$$Y(\theta) = Y_1(\theta) - Y_2(\theta)$$

$$= \frac{\alpha}{1 + \alpha} \exp(-R\theta) - \sum_{n=1}^{\infty} \frac{2 \exp(-R^2/\alpha)}{1 + \alpha + \beta^2/\alpha} - S(1-\exp(-R\theta))$$

$$= \frac{\alpha}{1 + \alpha} \exp(-R\theta) - \frac{2 \exp(-R^2/\alpha)}{1 + \alpha + \beta^2/\alpha} - S - \alpha R S$$

In like manner, equation (27) is repeated as

$$\bar{X} = \frac{\frac{\alpha}{1 + \alpha} \exp(-R\theta) - \frac{2 \exp(-R^2/\alpha)}{1 + \alpha + \beta^2/\alpha} - S - \alpha R S}{s + R}$$

$$= \bar{X}_1 - \bar{X}_2 - \bar{X}_3$$

where,

$$\bar{X}_1 = \frac{1}{s + R}$$

$$\bar{X}_2 = \frac{\sqrt{s + R} \cosh(\sqrt{s + R}(1 - \lambda))}{(s + R)[\sqrt{s + R} \cosh(\sqrt{s + R}) + \alpha \sinh(\sqrt{s + R})]}$$

$$\bar{X}_3 = \frac{R S}{s(s + R)}$$

The inverse transform of $\bar{X}$ can be expressed by inverse transforms of $\bar{X}_1$, $\bar{X}_2$ and $\bar{X}_3$. Then, the inverse transforms of $\bar{X}_1$, $\bar{X}_2$ and $\bar{X}_3$, i.e., $X_1(\theta, \lambda)$, $X_2(\theta, \lambda)$ and $X_3(\theta, \lambda)$ can be obtained by the same method used before. Finally, the following equations are derived:
\[ x_1(\theta, \lambda) = \exp(-R \theta) \quad \text{(C-26)} \]

\[ x_2(\theta, \lambda) = \frac{1}{1+\alpha} \exp(-R \theta) + \sum_{n=1}^{\infty} \frac{2 \cos(\beta_n (1-\lambda))}{\frac{\beta_n^2}{\alpha} \cos \beta_n} \exp(-\beta_n^2 R \theta) \]

\[ x_3(\theta, \lambda) = S(1 - \exp(-R \theta)) \quad \text{(C-27)} \]

Thus, by the substitution of equations (C-26), (C-27) and (C-28) into equation (27)

\[ x(\theta, \lambda) = x_1(\theta, \lambda) - x_2(\theta, \lambda) - x_3(\theta, \lambda) \]

\[ = \frac{\alpha}{1+\alpha} \exp(-R \theta) - \sum_{n=1}^{\infty} \frac{2 \cos(\beta_n (1-\lambda))}{\frac{\beta_n^2}{\alpha} \cos \beta_n} \exp(-\beta_n^2 R \theta) \]

\[ - S(1 - \exp(-R \theta)) \]

\[ \text{(29)} \]
APPENDIX. D.

DERIVATION OF EQUATIONS (35) AND (36)
FROM EQUATIONS (33) AND (34).
Equations (33) and (34) are repeated below:

\[
\frac{d^2\overline{X}}{d\lambda_1^2} - s\overline{X} + 1 = 0 \tag{33},
\]

\[
\overline{Y} = \frac{1}{s} \left. \frac{d\overline{X}}{d\lambda_1} \right|_{\lambda_1=0} \tag{34}.
\]

Boundary conditions are

1. at \( \lambda_1 = 0, \quad \overline{X} = \overline{Y} 
2. at \( \lambda_1 = \infty, \quad \overline{X} = \frac{1}{s}.

The homogeneous solution for equation (33) can be obtained as

\[
\overline{X}_h = a \exp(-\lambda_1\sqrt{s}) + b \exp(\lambda_1\sqrt{s}) \tag{D-1},
\]

where \( a \) and \( b \) are integral constants to be determined.

If the particular solution for equation (33) is assumed to be \( F \), then the general solution is expressed as

\[
\overline{X} = a \exp(-\lambda_1\sqrt{s}) + b \exp(\lambda_1\sqrt{s}) + F \tag{D-2}.
\]

In order to evaluate \( F \), equation (D-2) is substituted into equation (33), and equation (D-3) is obtained as follows:

\[
\frac{d^2\overline{X}}{d\lambda_1^2} - s\overline{X} + 1 = s[a \exp(-\lambda_1\sqrt{s}) + b \exp(\lambda_1\sqrt{s})]
- s[a \exp(-\lambda_1\sqrt{s}) + b \exp(\lambda_1\sqrt{s}) + F] + 1 = 0
\]

or

\[
F = \frac{1}{s} \tag{D-3}.
\]

By substituting equation (D-3) into equation (D-2), equation (D-4) is produced as follows:

...
Now the integral constants \( a \) and \( b \) must be determined with two boundary conditions. Boundary condition (1) implies that

\[
\overline{y} = a + b + \frac{1}{s}
\]  
(D-5).

Also, boundary condition (2) implies that

\[
b = 0
\]  
(D-6).

Thus,

\[
a = \overline{y} - \frac{1}{s}
\]  
(D-7).

By substituting equations (D-6) and (D-7) into equation (D-4), equation (35) is obtained:

\[
\overline{x} = (\overline{y} - \frac{1}{s}) \exp(-\lambda_1 \sqrt{s}) + \frac{1}{s}
\]  
(35).

Now the expression for \( \overline{y} \) is found by substituting equation (35) into equation (34). That is,

\[
\overline{y} = \frac{1}{s} \frac{d \overline{x}}{d\lambda_1} \bigg|_{\lambda_1 = 0}
\]

\[
= -\frac{\overline{y}}{\sqrt{s}} + \frac{1}{\sqrt{s} \sqrt{s}}
\]

or

\[
\overline{y} = \frac{1}{s(\lambda_1 \sqrt{s})}
\]  
(36).
APPENDIX. E.

DERIVATION OF EQUATIONS (41) AND (42)
FROM EQUATIONS (39) AND (40).
Here, analytical solutions for equations (39) and (40) are derived with three initial and boundary conditions. These equations are

\[ \frac{d^2 X}{d \lambda_1^2} = \frac{d^2 X}{d \lambda_1^2} - R_1 (X + S_1) \quad \text{(39)} \]

\[ \frac{d Y}{d \theta_1} - R_1 (X + S_1) = \frac{d X}{d \lambda_1} \bigg|_{\lambda_1=0} \quad \text{(40)} \]

with initial and boundary conditions,

(1) when \( \theta_1 = 0 \),

\[ X = 1 \]

and

\[ Y = 0, \]

(2) at \( \lambda_1 = 0 \),

\[ X = Y \quad \text{for} \quad \theta_1 > 0, \]

and

(3) at \( \lambda_1 = \infty \),

\[ \frac{d X}{d \theta_1} = -R_1 (X + S_1). \]

By making Laplace transforms of equations (39) and (40), and the initial and boundary conditions with respect to \( \theta_1 \),

\[ \frac{d^2 X}{d \lambda_1^2} - (s + R) \overline{X} + 1 - \frac{R_1 S_1}{s} = 0 \quad \text{(E-1)} \]

\[ (s + R_1) \overline{X} + \frac{R_1 S_1}{s} = \frac{d X}{d \lambda_1} \bigg|_{\lambda_1=0} \quad \text{(E-2)} \]

and transformed boundary conditions,
(1) at $\lambda_1 = 0$, \[ \bar{X} = \bar{Y} \]

(2) at $\lambda_1 = \infty$, \[ \bar{X} = \frac{s - R_1 S_1}{s(s + R_1)} \]

are obtained.

With the same method used in Case (III), one can get the general solution for equation (E-1) as follows:

\[ \bar{X} = a \exp(-\lambda_1 \sqrt{s + R_1}) + b \exp(\lambda_1 \sqrt{s + R_1}) + \frac{s - R_1 S_1}{s(s + R_1)} \]  \hspace{1cm} (E-3).

Now arbitrary constants $a$ and $b$ are determined with the two boundary conditions above. Boundary condition (1) implies that

\[ \bar{Y} = a + b + \frac{s - R_1 S_1}{s(s + R_1)} \]  \hspace{1cm} (E-4).

Boundary condition (2) implies that

\[ b = 0 \]  \hspace{1cm} (E-5).

Thus, \[ a = \bar{Y} - \frac{s - R_1 S_1}{s(s + R_1)} \]  \hspace{1cm} (E-6).

By substituting equations (E-5) and (E-6) into equation (E-3),

\[ \bar{X} = (\bar{Y} - \frac{s - R_1 S_1}{s(s + R_1)}) \exp(-\lambda_1 \sqrt{s + R_1}) + \frac{s - R_1 S_1}{s(s + R_1)} \]  \hspace{1cm} (E-7)

is obtained.

Now the expression for $\bar{Y}$ is found by the substitution of equation (E-7) into equation (E-2) as follows:

\[ (s + R_1) \bar{X} + \frac{R_1 S_1}{s} = \left. \frac{d\bar{X}}{d\lambda_1} \right|_{\lambda_1 = 0} \]

\[ = (-\lambda_1 \sqrt{s + R_1})(\bar{Y} - \frac{s - R_1 S_1}{s(s + R_1)}) \]
or \[ \bar{Y} = \frac{1}{(s+R_1)(\sqrt{s+R_1} + 1)} - \frac{R_1 S_1}{s(s+R_1)} \] (E-8).

The inverse Laplace transform of \( \bar{Y} \), \( Y(\theta_1) \), can be obtained by using the Table of Inverse Laplace Transformation (11) as follows:

\[
Y(\theta_1) = \exp(-R_1 \theta_1) - \exp((1-R_1)\theta_1) \text{erfc}(\sqrt{\theta_1})
- S_1(1 - \exp(-R_1 \theta_1))
\] (41).

By substituting equation (E-8) into equation (E-7), the following equation is obtained.

\[
X = \frac{1}{s+R_1} - \frac{\exp(-\lambda_1\sqrt{s+R_1})}{\sqrt{s+R_1}(\sqrt{s+R_1} + 1)} - \frac{R_1 S_1}{s(s+R_1)}
\] (E-9).

Also, the inverse form of \( \bar{X} \), \( X(\theta_1, \lambda_1) \), can be found as

\[
X(\theta_1, \lambda_1) = \exp(-R_1 \theta_1) - \exp(\lambda_1 + (1-R_1)\theta_1) \text{erfc}(\sqrt{\theta_1 + \frac{\lambda_1}{2\sqrt{\theta_1}}})
- S_1(1 - \exp(-R_1 \theta_1))
\] (42).
APPENDIX. F.

DERIVATION OF THE ANALYTICAL SOLUTION FOR CASE (11) BY USING DIMENSIONLESS GROUP, EQUATION (10.a).
In Case (II), equations (4) and (5) are repeated as

\[
\frac{\partial c}{\partial t} = D_e \frac{\partial^2 c}{\partial z^2} - kc \tag{4},
\]
\[
V \frac{dc_1}{dt} = D_e \frac{\partial c_1}{\partial z} \bigg|_{z=0} Pa - Vkc_1 \tag{5}.
\]

The initial and boundary conditions are

(1) when \( t = 0, \)
\[
c = c_1
\]
and
\[
c_1 = c_{11},
\]
(2) at \( z = 0, \)
\[
c = c_1 \quad \text{for} \quad t > 0,
\]
and
(3) at \( z = L, \)
\[
\frac{\partial c}{\partial z} = 0.
\]

By introducing the dimensionless group, equation (10.a), into equations (4) and (5) and the initial and boundary conditions, the following equations (F-1) and (F-2) can be obtained

\[
\frac{\delta X}{\delta \theta_1} = \frac{\delta^2 X}{\delta \lambda_1^2} - R_1(X + S_1) \tag{F-1}
\]
\[
\frac{dY}{d\theta_1} + R_1(Y + S_1) = \frac{\delta X}{\delta \lambda_1} \bigg|_{\lambda_1=0}, \quad \text{for} \quad \theta_1 > 0 \tag{F-2}
\]

with new initial and boundary conditions,

(1) when \( \theta_1 = 0, \)
\[
X = 1
\]
and

\( Y = 0, \)

(2) at \( \lambda_1 = 0, \)

\( \alpha = Y \quad \text{for } \theta_1 > 0, \)

and

(3) at \( \lambda_1 = \alpha, \)

\[ \frac{dX}{d\lambda_1} = 0, \]

where

\[ R_1 = \frac{kL^2}{D_e \alpha^2}, \]

\[ S_1 = \frac{c\lambda_1}{c_1 - c\lambda_1}, \]

and

\[ \alpha = \frac{\Delta P}{V}. \]

Laplace transforms of the equations (F-1) and (F-2) are

\[ \frac{d^2X}{d\lambda_1^2} - (s + R_1)X + 1 = \frac{R_1 S_1}{s} = 0 \quad \text{(F-3)} \]

and

\[ (s + R_1)X + \frac{R_1 S_1}{s} = \left. \frac{dX}{d\lambda_1} \right|_{\lambda_1=0} \quad \text{(F-4)}. \]

Also, the transformed boundary conditions are written as

(1) at \( \lambda_1 = 0, \) \[ \Xi = \overline{Y} \quad \text{for } \theta_1 > 0 \]

(ii) at \( \lambda_1 = \alpha, \)

\[ \frac{d\overline{Y}}{d\lambda_1} = 0. \]
The general solution for equation (F-3) can be obtained by the same method shown in Case (II); that is,

\[
\chi = \frac{s - R_1 S_1}{s(s + R_1)} \left[ \exp((2\alpha - \lambda_1)\sqrt{s + R_1}) + \exp(\lambda_1\sqrt{s + R_1}) \right]
\]

\[
+ \frac{s - R_1 S_1}{s(s + R_1)}
\]

(E-5).

Accordingly,

\[
\chi = \frac{\exp(2\alpha \sqrt{s + R_1}) - 1}{(s + R_1)\left[ \sqrt{s + R_1}(\exp(2\alpha \sqrt{s + R_1}) + 1) + (\exp(2\alpha \sqrt{s + R_1}) - 1) \right]}
\]

\[
- \frac{R_1 S_1}{s(s + R_1)}
\]

(E-6).

Since

\[
\exp(2\alpha \sqrt{s + R_1}) - 1 = 2 \exp(\alpha \sqrt{s + R_1}) \sinh(\alpha \sqrt{s + R_1})
\]

and

\[
\exp(2\alpha \sqrt{s + R_1}) + 1 = 2 \exp(\alpha \sqrt{s + R_1}) \cosh(\alpha \sqrt{s + R_1}),
\]

equations (E-6) and (E-5) become

\[
\chi = \frac{\sinh(\alpha \sqrt{s + R_1})}{(s + R_1)\left[ \sqrt{s + R_1} \cosh(\alpha \sqrt{s + R_1}) + \sinh(\alpha \sqrt{s + R_1}) \right]} - \frac{R_1 S_1}{s(s + R_1)}
\]

(E-7)

and

\[
\chi = \frac{1}{s + R_1} - \frac{\sqrt{s + R_1} \cosh((\alpha - \lambda_1)\sqrt{s + R_1})}{(s + R_1)\left[ \sqrt{s + R_1} \cosh(\alpha \sqrt{s + R_1}) + \sinh(\alpha \sqrt{s + R_1}) \right]}
\]

\[
- \frac{R_1 S_1}{s(s + R_1)}
\]

(E-8).
By the same procedure as that in Appendix (C), the inverse Laplace transforms of $\bar{Y}(s)$ and $\bar{W}(s, \lambda)$, $Y(\theta_1)$ and $X(\theta_1, \lambda_1)$, can be obtained as follows:

$$Y(\theta_1) = \frac{\alpha}{1+\alpha} \exp(-R_1 \theta_1) - \sum_{n=1}^{\infty} \frac{2}{1+\alpha+\alpha \delta_n} \exp(-\delta_n^2 + R_1 \theta_1) - S_1(1 - \exp(-R_1 \theta_1)) \tag{F-9}$$

and

$$X(\theta_1, \lambda_1) = \frac{\alpha}{1+\alpha} \exp(-R_1 \theta_1) - \sum_{n=1}^{\infty} \frac{2 \cos[\delta_n^2 (\alpha - \lambda_1)]}{(1+\alpha+\alpha \delta_n^2) \cos \alpha \delta_n} \exp(-\delta_n^2 + R_1 \theta_1) - S_1(1 - \exp(-R_1 \theta_1)) \tag{F-10}$$

where $\delta_n$ satisfies

$$\cot(\alpha \delta) + 1 = 0 \tag{F-11}.$$

Compute \( E(X_2) \)

\[ d = X_1 \quad \text{No} \]
\[ E(X_1) - E(X_2) \leq 0 \quad \text{Yes} \]
\[ c = X_2 \]

\[ X_1 = X_2 \]
\[ E(X_1) = E(X_2) \]

\[ X_2 = c + d - X_1 \]

Compute \( E(X_2) \)

\[ d - c \leq \text{ERR} \quad \text{No} \]
\[ X_1 = c + d - X_2 \]

Compute \( E(X_1) \)

\[ d - c \leq \text{ERR} \quad \text{Yes} \]

Write \( X_1, X_2, c, d, E(X_1) \) & \( E(X_2) \)

Stop

MASTER OF SCIENCE

Department of Chemical Engineering

KANSAS STATE UNIVERSITY
Manhattan, Kansas

1969
It has been shown that runoff from cattle feedlots is a significant source of water pollution in the Midwest, where commercial cattle feeding has grown rapidly. In the runoff stream, the chemical oxygen demand (COD) is one measure of the concentration of the organic components which contaminate water.

To determine the transport rate of manure through a porous stratum saturated by water under the simulated condition of the feedlot, a mathematical model of the system consisting of the soil-manure packed bed saturated by water and the well mixed solution on the bed was established. For this mathematical model, the system equations and the corresponding initial and boundary conditions were derived for several cases. For those cases, the analytical expressions for the concentrations within the packed bed and in the upper solution were obtained as the function of time and distance from the interface of the two layers and as the function of time respectively.

To apply the experimental set-up of the mathematical model for the purpose of determining the transport rate of manure as measured by its COD through the porous bed, the experimental set-up was tested and calibrated by the experiments with an aqueous sucrose solution of known diffusivity. It was shown that a single correction factor in terms of the depth correction factor satisfactory corrected the effects due to the initial disturbance and the continuous convective motion of the fluid.

The experimental system which had been characterized as
The effective diffusivity (effective pseudo-molecular diffusivity) of manure as measured by its COD was found to be approximately $5.02 \times 10^{-5}$ cm$^2$/sec at the temperature of $25.2$ °C. This corresponds to a molecular (pseudo-molecular) diffusivity of $7.10 \times 10^{-6}$ cm$^2$/sec.

Information generated in this study is pertinent to water pollution caused by feedlot runoff. Since the effective diffusivity (effective pseudo-diffusivity) of manure through a porous stratum is small, it can be said that organic matter which diffuses from the earth beneath the feedlot to the surface of the feedlot does not probably contribute seriously to the pollution due to the feedlot runoff. It may be concluded that as far as COD is concerned, manure suspension in the runoff water contributes mainly to water pollution. This work can also be applied to study the effect of diffusivity of a substance in the process of fluid flowing through a porous bed such as soil.
