I. INTRODUCTION

A. OVERVIEW

This report describes a system driver designed for the Chromatics CG (Computer Graphics) 1999. The program allows the user to extend the performance of the Chromatics in two primary areas: input capability and extension of graphics primitives.

Using Chromatics commands under program control, the interface suppresses keys which would kill the program while redefining some keys for new commands.

Coordinate input for graphics primitives is accepted in any of four modes:

(1) from the keyboard as digit coordinates,
(2) from the keyboard as cursor position,
(3) from the tablet, positioning from the four-button cursor on the tablet,
(4) from the tablet, positioning from the cursor on the screen.

The program expands the set of graphics primitives available. While built-in primitives such as circles and rectangles are available on the Chromatics itself, extended primitives such as thickened lines and arrows are accessed from disk using an overlay.

A Users' Guide is provided along with sample programs and diagrams which illustrate the use of the driver. Source code and details related to programming options give opportunity for modification to suit individual applications.
B. PAPER ORGANIZATION

Chapter one is an introduction which provides some background information and describes the general project effort, results and evaluation.

Chapter two is a Users' Guide for the resultant program. It is intended for the reader who desires to use the driver on the Chromatics color graphics microcomputer.

Chapter three provides details of the program development which would enable the reader either to duplicate the interface or modify it to expand the subset of graphics primitives, rescale the tablet, redefine the function keys or add other features not included in this project.

Appendices include the source code for the system driver and sample programs that support or expand upon various items in the text of chapters one, two and three.

C. BACKGROUND

In 1972 the Computer Science Department of Kansas State University acquired a Computek graphics terminal. It was a dumb terminal, black and white with 256 x 256 discrete points and required 8K of refresh memory.

By 1978 a Compucolor 8080-based terminal with eight colors, light pen, mini disks and 64K of memory was added. Its 160 x 190 discrete points required 15K of refresh memory; about 48K of memory was available to the user.

The further addition in summer, 1979, of a Chromatics 280-based terminal with two disk drives, tablet, and high resolution from 512 x
512 discrete points expanded opportunities for more sophisticated work in color graphics. While the refresh memory alone required 131K, about 40K of memory was available for BASIC users.

Through the efforts of students in the fall 1979 KSU graphics class and the work of several other individuals, the capabilities and possibilities of the KSU graphics systems have become increasingly diversified. The past year has included development of demonstration programs, Chromatics hardcopy capability with an interface to the Perkin-Elmer minicomputer printer, and introductory users' guides for the Chromatics graphics functions. Current efforts include developing a comprehensive users' manual. attaching a camera, expanding the set of primitives available, working toward hard copy color graphics materials and developing editing capability for the create buffer.

This paper is a report on one additional step in the development of a comprehensive graphics system at KSU.

D. MOTIVATION

Human Engineering

The decision to undertake this particular project resulted primarily from short-range considerations. There were many respects in which the graphics system as it was did not provide a very "human" interface for users.

Documentation was scattered within more than four different manuals. In various instances the documentation was confusing, non-existent, or even inaccurate. Although production of a comprehensive, usable set of instructions for the whole Chromatics system was considered beyond the scope of this research, it was desired
to produce a guide which would simplify and organize the information necessary to successfully execute a program such as the one described in this report.

Use of the tablet was limited as there was inadequate software available to link the tablet to the full range of keyboard possibilities. Providing a smooth interface would allow users to input information from the tablet while intermixing the usual keyboard commands and data.

Some keys or input sequences would cause undesirable effects or even kill the program; these possibilities needed to be avoided while at the same time providing users the opportunity for some changes of mind in order to provide a tolerant environment.

Several improvements and additions to the system were hoped for. Separate work was in progress on routines to expand the basic set of graphics primitives; there needed to be some way to make these available to users. One of the most often used primitives, the circle, contained a "flaw" in one mode of inputting coordinates. A few changes would allow the user much greater accuracy and flexibility in defining circle size. Certain special function keys could be programmed for special effects to offer a greater range of easy-to-use features.

Learning and Extension

Very little existed in the way of documented programs which would encourage student experimentation and learning. The Computer Science Department could benefit from a model which could be "played with" and "added to" by students. Development of a driver for the Chromatics would provide another layer to the "onion" of software available for
such purposes.

Remote Teaching

One future possibility for use of graphics packages such as this one is in helping to provide visual aids for remote teaching. As features such as a camera, hard copy in color, etc., become available, demand for easy-to-use methods of producing quality graphics materials will increase.

E. DESCRIPTION OF PROJECT

Program Structure

The program, written in BASIC, consists of four parts (see Figure 1, page 6). The initialization in "Part 1" is executed only once; at its conclusion "Part 2", the Main Driver, is loaded. If the user requests extended graphics primitives (basic figures generated by special software routines) control moves to "Part 3" or "Part 4" which contain the routines for WIDE_VECTOR, SLANT_RECTANGLE, ARROW, and DOUBLE-HEADED_ARROW. These extended graphics routines were developed at Kansas State University by Maxine Yee (Yee80) and they are a significant contribution to the development of this report.

The main driver of the program is a simple interrupt handler (see Figure 2, page 6). Input is accepted from the keyboard one character at a time. A large case statement constructed of "if-then" statements checks the input and branches to the appropriate place in the program. The main driver handles state changes such as "blink" and "fill", color changes, and selects and sets up the primitives.

Coordinates for the primitives are gathered by a subroutine which
FIGURE 1.

END CYCLE

(*"PRINT" outputs to Chromatics software)
accepts input from the keyboard using the cursor position on the screen, from the keyboard using digits, from the tablet using the cursor position on the screen and from the tablet using positioning of the four-button cursor on the tablet.

The tablet is available on reprogrammed keys in either of two modes: stream mode or point mode. Stream mode inputs coordinates at the rate of 70 x-y pairs per second and facilitates tracking of the cursor on the screen as well as small increments in primitives such as the concatenated vector. Point mode inputs a single coordinate pair at a time. The position of the four-button cursor does not appear on the screen since the positioning in this mode needs to come from the tablet. Since only one point is input at a time, the chance of an error in coordinate selection due to holding the button down too long is eliminated.

A "create buffer" is available in the main driver. If the user selects this option the program itself handles turning the buffer off and on to eliminate the storage of unnecessary information (such as cursor movements) which might fill up the buffer space. Data in the create buffer may be redisplayed on command or saved as a file on disk.

Extensibility of the set of primitives is demonstrated with "Part 3" and "Part 4", overlay routines called by the main program (see Figure 3, page 8). Coordinates are fetched and stored in an array before the overlay is loaded; at the conclusion of an overlay routine the main driver is reloaded and the program continues. The relationship of this program to the underlying Chromatics software is illustrated in Figure 4, page 8.

RELATIONSHIP TO CHROMATICS SOFTWARE
Evaluation of Results

The primary objective was achieved in that the program provides an easy way to produce a graphics file. The user is afforded a reasonable set of primitives which can handle a wide range of applications. Many functions which previously required a sequence of instructions have been programmed to operate through use of a single key which has been redefined specifically for one purpose. For example, the eight function keys on the top right of the Chromatics keyboard combine the complex fill commands with characters from the alternate character set to give special shading effects. This feature could be particularly useful in maps or graphs.

A smooth transition is provided from tablet to keyboard, and vice-versa, with pre-set initialization simplifying use of the tablet. Switching from stream to point mode requires only a single key.

A relatively tolerant environment has been achieved. Input which kills the program appears to have been successfully "weeded out". Once a primitive has been designated, attempts to select a new primitive are ignored until the correct number of coordinates has been received and the original primitive has been printed. This helps ensure correct completion of primitives and prevents the program from stacking up a large number of subroutine calls for coordinates. However, users can redecide a "state" at any time, even in the midst of gathering coordinates, or even "cancel" the primitive in progress.

Although the program prevents the user from turning off plot mode while getting coordinates from the screen, the same precaution did not appear to work from the tablet. Therefore, plot control needed to be available when the tablet was enabled so that if plot was turned off,
the user could restore plot mode before continuing coordinate input.

Another difficulty became obvious when using the tablet for copying. The square tablet with equal X and Y distances between points caused distortion when figures were transferred to the rectangular screen having unequal X and Y distances.

Some optimization was done on the create buffer so that only the minimum set of instructions needed to reproduce the display was stored in the create buffer.

The program is composed of small, identifiable modules. Similar code is grouped together and duplication avoided where possible. Use of a single subroutine for coordinates channels all coordinate requests to the same place even though there are four options in the way coordinates may be gathered. The structure makes the code easy to comment, easy to read and easy to modify. This feature should enhance the objective relative to student learnings and extensibility of the program.

Learnings

Experience in developing the software for the project yielded lessons in: (1) the equipment, (2) the language, (3) graphics, (4) use of commercial documentation and (5) programming techniques.

Many aspects were "first-time" experiences: using a microcomputer, programming in BASIC, using graphics functions, using floppy disks, using a tablet, working with an alternate character set, designing an interrupt service routine, doing overlays and having to use source code as a mini-manual. "GO-TOs" had always been frowned on and had never really been necessary in previous programming experience. In BASIC, however. GO-TOs were essential but required effective use of block
structure and branching mechanisms. Logical to physical device assignments had to be made and rate codes set.

There was a heavy demand for experimenting and finding out what worked. Interactive debugging required special techniques such as inserting delays to allow time to monitor responses. Chromatics function keys had to be trapped to determine their special code on the machine so that their action could be redefined.

The 170 or so lines of code which contain the final product are too few to really be indicative of the learning which occurred.
II. USERS' GUIDE

A. THE MACHINE

1. The Screen

   The CRT (cathode ray tube) screen (see sketch of terminal in Figure 5, page 13), is logically a rectangular grid of 512 x 512 points. It is helpful to image it as a coordinate graph where the X-axis goes from 0 to 511 and the Y-axis likewise goes from 0 to 511 (see Figure 5, page 13). Any pair of coordinates within this range is represented physically by some particular point on the screen, called a pixel (from "picture element"). The X coordinate represents the horizontal displacement from the lower left hand corner (the origin) and is always assumed to be the first element of the coordinate pair. The Y coordinate represents the vertical displacement up from the origin and is assumed to be the second element of the coordinate pair: (X,Y). If coordinate values higher than 511 are entered the result is the same as if these coordinates modulo 511 had been entered. For example: entering (700.800) would give the same result as entering (189,289).

   The width and height of the CRT screen display area are not in the same ratio as the number of X dots and Y dots; five X dots approximately equal seven Y dots.

   A window is logically a rectangular subset of the points displayed on the CRT screen. A single window defined as the full screen size is what the user sees. It is possible to define four overlapping windows (see USERS' GUIDE, Section E.4, for information on multiple windows).
FIGURE 5.

FIGURE 6.
THE DISPLAY SCREEN
FIGURE 7.
CHROMATICS DISK DRIVES

FIGURE 8.
DISKETTE
FIGURE 9.
THE TABLET

FIGURE 10.
4-BUTTON CURSOR
2. The Disks

The KSU Chromatics CG terminal has two disk drives attached (see Figure 7, page 14). Information is stored on eight-inch, single-density floppy disks (Figure 8, page 14) in concentric rings. New disks need to be formatted before use; check the Chromatics Disk Software Reference Manual (Chr78a), subsection 2.5.6, if you have an unformatted disk.

If the "create" option in this program is selected, graphics produced may be saved on disk as a buffer file. Sample Sessions in the appendix illustrate the saving of buffer files.

3. The Tablet

The tablet (see Figure 9, page 15) is conceptually similar to the screen described above. It is square in shape with raw coordinates ranging from (0,0) to (2200,2200). Here the X and Y distances are in a one to one ratio. Consequently, transferring pictures on a square tablet to a rectangular screen requires a scaling transfer. (For more information on scaling see page 57.)

The program documented in this report automatically maps the tablet onto the screen and coordinates may be input directly by using the 4-button cursor.

When the tablet is enabled, use the 4-button cursor by lining up the crosshairs over the desired point and pressing the topmost button for a "hit" (see Figure 10, page 15). When a point is selected on the tablet (and Point Mode is NOT enabled), a dot remains on the screen to mark the "hit". This "remembering" of points selected allows the user to place subsequent points in relationship to to those already selected. If it is later desired to remove any extra dots, they may be "erased" by
lining up the cursor dot over the dot on the screen and overwriting with a dot of the background color.

The bottom button on the cursor is used to complete the selection of coordinates for certain primitives, such as the concatenated vector, where the desired number of coordinates is not known ahead of time. In addition, non-concatenated primitives may be "cancelled" by using the bottom button, which signals termination of the primitive. The other two buttons on the cursor are not used in this program and will give no effect when pressed.

B. THE PROGRAM

1. Initial Conditions

The program begins with an ERASE PAGE and sets up the following initial conditions:

- window size: full screen
- colors: foreground=green; background=black
- cursor: green, in home position
- BLINK off, ROLL off, PLOT on, FILL off.
- BACKGROUND off, CREATE off
- TABLET off, OVERSTRIKE off
- Character mode (not accessible until PLOT is off):
  character size 1 by 1, standard character set, horizontal mode

2. Loading and Running

- Insert disk into disk drive with label side up and with label
toward you, until the disk clicks and stays in place. Pull latch
down to lock in the disk.

* Push "on" light on Chromatics and on disk drive, so that both
  lights appear lighted (refer to Figure 5, page 13, and Figure 7,
  page 14).

* Push RESET, BOOT/WIDE_VECTOR, BASIC/SLANT_RECT, and RETURN. The
  last item on the screen should be a prompt in green which says,
  "OK".

* Push the reset button on the right side of the tablet to reset it
  to initial states (refer to Figure 9, page 15). If you fail to do
  this you may get a "TYPE MISMATCH" error the first time you try to
  use the tablet.

* Type `DOS'LOAD PART1'; push RETURN. The machine will load the
  program and return with the prompt "OK".

* Type `RUN'; push RETURN. Wait a minute to allow Part 1 to finish and
  load Part 2. (When the red light on the disk drive goes out the
  loading is complete.) The machine will begin execution of the
  program and set initial conditions: the "plot key" should be
  lighted and all others unlighted while the cursor for plot, 
  ",,", should appear at the upper left of the screen in home position.

You are now ready to enter commands. Select commands from the Key
Summary (Figure 11, pages 20-22) or consult the remaining sections of
this chapter for additional information on how the various keys work.
Also, the Sample Sessions in the Appendix demonstrate many of the
commands. When finished with your session simply push the BREAK key
and, if desired, save your file using DOS commands.

Extensions for editing, saving and retrieving display files are
currently being developed by Sharlene Mitchell.

**NOTE:** The remainder of this chapter contains a condensed, reorganized and corrected version of portions of the Chromatics Preliminary Operator's Manual. Information useful for this program has been included while unnecessary sections or details have been omitted.

C. THE KEYBOARD AND THE COMMANDS

1. Introduction to the Keyboard

The keyboard is the primary input device for the terminal. If a key is held for about 3/4-ths of a second, the key is repeated.

There are four groups of keys on the 128-key keyboard (see Figure 12, page 24). The upper three rows are special function keys, used for functions specifically defined for the Chromatics CG series or redefined for this particular program. The numeric keypad is the block of keys on the lower right; it is arranged in adding machine format to allow easy entry of numeric information and equations. The group of five keys to the left of the numeric keypad is the cursor control, which allows for easy positioning of the cursor anywhere on the screen. The final group of keys is the basic keyboard, which is the typewriter-like block of keys on the lower left.

Since the program requires a significant amount of checking on each input character, typing too fast may cause some input to be skipped—be sure your input rate is acceptable.

2. Redefined Keys

Several of the special function keys have been redefined for special uses in this program. (Redefined keys appear with the new definitions in lower case letters above the original key definitions in Figure 12.) The user may wish to tape over those keys and mark them with the new symbols. The new keys and their actions are given in the table in Figure 13, page 25.

**FIGURE 13.**
3. **Shift**

Shift provides access to two alternate character sets: lower case for the basic keyboard and an alternate character set (as shown in Figure 15b, page 35), if the command for the alternate character set has been issued. (See Section D.2 on CHARACTER MODE.)

Shift in combination with the cursor control keys moves the cursor only one dot (pixel) in the direction indicated instead of the usual six dots left/right or ten dots up/down.

Shift also has a special use in combination with control for two codes, underline and delete in which SHIFT must be held down while pressing CONTROL. The sequence is:

```
SHIFT  CTRL / = _ (underline)
SHIFT  CTRL 0 = DEL (delete symbol,
                 a non-printing symbol)
```

4. **States**

States define the status of a window.

**Colors** - Colors are set by pushing the color keys.

**Background** - The Background command sets background mode on and lights the BACKGROUND key. Future color commands will affect the background color. Pushing the key a second time sets background mode off so that future color commands will now affect the foreground color.

**Blink** - The Blink command lights the BLINK key and sets the screen to foreground blink (or background blink if the BACKGROUND key is lighted). Pushing the key a second time turns off the light and resets to non-blink mode. The following set of
commands provides an example of the variations possible using 

BLINK:

BOOT   MODE X 5,   MODE Y 5,   BACKGROUND
BLUE   ERASE PAGE  CYAN   BACKGROUND(off)
RED    -->   -->   ↓   ↓   F   BLINK   -->
F   BACKGROUND   -->   BACKGROUND(off)
BLINK(off)   -->   F

When entered correctly, all four possibilities for blinking should be displayed: the first character should be a large red "F" on a cyan block; the second character is a blinking, red "F"; in the third character both the "F" and the background blink; and in the fourth character only the background blinks while the letter "F" is stationary.

**Fill** - The Fill command lights the FILL key and subsequent primitives will appear in solid color (all interior dots lighted) rather than in outline form. Pushing the FILL key a second time turns off the light and resets the state to non-fill.

**Dotted Line** - The Dotted Line command is available as a state option for wide vectors and arrows. If the CTRL D sequence is pushed and the next primitive to be printed is a wide vector or an arrow, the primitive will appear with dotted (dashed) lines. This state, or attribute, needs to be reselected each time it is to be used.

**Tablet** - Use of the Tablet command changes coordinate input for primitives from the keyboard as a source to the tablet. In stream mode (the default tablet submode), the coordinate
position of the cursor is continually sent to the screen so that the user may follow the movement of the cursor. However, if the top button on the cursor is pressed, a "hit" is recorded and the coordinates at the position of the hit are selected. Care must be taken in doing selection; if the cursor is moved even slightly during a "hit", additional coordinates are likely to be selected.

**Point Mode** - This tablet submode may be selected by pushing the POINT MODE key. The cursor position is no longer tracked on the screen and one pair of coordinates is selected at a time by pushing the top button. Point mode is less risky than stream mode since a "hit" is guaranteed to pick up only one pair of coordinates. This submode is useful when a figure is to be copied: simply tape your paper securely to the tablet itself and select the appropriate primitives. An illustration of the use of POINT MODE is presented in Sample Session 2 in the Appendix.

**ROLL** - When the Roll key is lighted the information in the window is automatically scrolled up (or down) as the cursor moves past the bottom (or top) of the window. If the user is entering text this is particularly useful. For most graphics applications, however, it is dangerous in that a roll state could lose the contents of the topmost (or bottommost) lines of the window; therefore this program initializes the roll state to "off" and it is recommended that the user only enable roll with caution.

**Plot** - All graphics primitives become active in PLCT mode. When
the machine is in Plot state, the PLOT key light is on and the cursor is displayed as a blinking dot followed by a line. This form of the cursor reminds the user of the current state and enables selection of a particular pixel.

Pushing the PLOT key so that the light is turned off returns the machine to Character Mode and also acts as a mode cancel by ignoring any partially entered mode commands.

5. Mode Codes

Mode code functions are used to establish the operating mode of a window. If no windows have been defined, the mode codes describe the whole screen which is the window #0. The more common mode codes follow:

Character Size - The character size can be expanded an integer number of times in either the horizontal or vertical directions. The format is

MODE X num1, MODE Y num2.

Keying "MODE X2, MODE Y3." for example, changes the dimensions of the characters displayed to twice the width and three times the height. The maximum value of num1 is 85 and the maximum value of num2 is 51.

Example key sequence:

A B C RETURN LF LF
MODE Y 3, A B C RETURN LF LF
MODE X 3, A B C

When keyed correctly, this sequence should produce three lines with "ABC" displayed. The first line is normal sized, the second tall and narrow and the third, normal characters three
times larger in both dimensions. To return to normal character size simply key in "MODE X1, MODE Y1, ".

**Vertical Display of Characters** - Occasionally it is convenient to display the characters vertically down the page. "MODE V" sets for vertical mode.

Example key sequence:

A B C   MODE V   A B C

This should result in:  
ABCA
B
C

To return to horizontal mode simply key in "MODE H".

**Interline Spacing** - Normally, each line of characters is directly adjacent to the line of characters above it. "MODE A num" sets the number of points between lines of characters to num (range 0 to 255). The default value of num is 0, so "MODE A 0" resets interline spacing to normal.

Note that the lines of points between characters are not written, (set to foreground or background color), when characters are sent with non-zero interline spacing. An ERASE PAGE command, however, will always set all window lines to background color.

**Cursor Display Control** - The cursor may be made invisible on the screen by keying "MODE K". However, the cursor still exists and will be moved by the appropriate commands. To make the cursor visible and blinking again, enter "MODE J". To change the cursor color enter "MODE Q colnum" where colnum is 0|1|2|3|4|5|6|7 and the color numbers match the order of color keys on the keyboard moving from left to right.
Erase Line - The "MODE " command causes the current line to be cleared to the background color; the cursor is not moved.

Erase to End of Line - The "MODE 3" command causes the remainder of the current line from the cursor to the right hand edge of the window to be erased to background color; the cursor is not moved.

Overstrike - The command "MODE 0" (notice this is 0 and not zero!) places the window in overstrike mode for the next display character. Only the foreground dots of the character are written; this allows multiple characters to be overlapped in the same location. The command "MODE ]" places the window in overstrike mode for all subsequent characters until overstrike mode is turned off. This function is useful in underlining as well as in special applications. "MODE [" places the window in normal (not overstrike) mode. An example key sequence is given:

```
MODE X 3, MODE Y 3, -- > -- > -- > ↓ ↓ ↓  
BACKGROUND BLUE BACKGROUND (off)  
CHR O M AT I CS RETURN -- > -- > -- >  
RED MODE ] SHIFT CTRL / SHIFT CTRL /  
SHIFT CTRL / SHIFT CTRL / SHIFT CTRL /  
SHIFT CTRL / SHIFT CTRL / SHIFT CTRL /  
SHIFT CTRL / MODE [  
```

Text - The command "MODE T char" causes an ERASE PAGE followed by the filling of the window with the indicated character (char), which cannot be a control character. (See the first example
in section E.4 on Windowing.)

**Delay** - The command "MODE ? num", where num is the duration of the
delay in tenths of a second and must be three digits long,
causes a delay in execution. (Example: if num = 050 the
delay is 5 seconds.) This command could be useful in
animation sequences as any delay from 0 up to 99.9 seconds is
possible. However, if this command is put into the create
buffer, expect to wait it out!

6. **Control Codes**

Most control functions can be keyed using the special function
keys. The following functions can only be keyed using the CTRL key:

- **CTRL A** = end of file (EOF)
- **CTRL W** = insert character
- **CTRL F** = delete character
- **CTRL B** = fixed-head option for arrow or double-headed arrow
- **CTRL C** = cancel last primitive
  
  (if entering tablet coordinates, use bottom button
  on cursor to cancel the last primitive)
- **CTRL D** = dotted line mode for extended primitives

**TABULATION** is set up on multiples of eight and is accomplished by
keying "CTRL I". The cursor is then moved to the next character
position on the current line which has a number divisible by eight,
where the numbers are assigned left to right beginning with the first
character position. If this action would move the cursor outside the
window, the cursor is moved to the first character position on the next
line; if the next line would be outside the window, the cursor is moved
to the Home position.

Another significant use of the CTRL key includes access to the alternate character sets. Pushing "CTRL N" turns on a signal so that all characters are taken from the alternate character set (see Figures 15a and 15b, pages 37 and 38). The command "CTRL O" turns the signal off, (the normal condition), and causes all characters to be taken from the standard set (as shown in Figure 12).

7. **Escape Codes**

Escape code functions are used primarily for high level control functions such as making logical to physical device assignments and transferring control between various main programs. The only application of escape codes to this program is windowing, discussed in Section E.4, and escape codes used with the create buffer, discussed in Section E.1.

8. **Miscellaneous Keys**

Keys not previously explained are noted below:

**ERASE PAGE** - This key clears the window.

**BREAK** - The only action taken for this key is a break in an output line created by a timing delay. The system will leave the BASIC program and allow the user to do editing and enter commands. (For an illustration of using this key to leave the program and enter commands to save the create buffer, see Sample Session 1, Part III.)

**LF** - Line feed moves the cursor to the position immediately below the current one. This command is identical to the down arrow,
HOME - The cursor is moved to the first character position of the top line.

CURSOR X-Y - The cursor is moved directly to the coordinates indicated:

    CURSOR X-Y coord coord

where "coord" represents a three-digit number. This command ignores window boundaries and should be used with care.

RESET - The RESET key is different from all other keys on the keyboard. It is a system control function which gains control from a program without losing internal information. It returns the system to the basic operating program supplied with the standard system.

BOOT - This key is like RESET but it additionally causes all devices and tables in the system to be initialized to default conditions. Sometimes a RESET preceding the BOOT is necessary for proper operation.

DISK OS - The DOS (Disk Operating System) allows the user to manipulate data to and from the floppy disk drives. DISK OS (DOS) prompts the user with an asterisk (*) to indicate that a disk command is expected. Some of the more useful DOS commands are:

- DIR - Type DIR, push RETURN, and the directory of files on your disk is displayed.

- BUFF - Type BUFF filename, push RETURN, and the create buffer is saved as a buffer file on your disk.

- DRAW - Type DRAW filename, push RETURN; when the prompt
(*) reappears the file is loaded. Push REDRAW and the file is displayed on the screen.

The DOS commands may also be executed under BASIC by typing DOS* command and then pushing RETURN. See the examples in the Sample Sessions or consult (Chro78a) for more information.

D. THE PRIMITIVES

1. Graphics Mode

The intrinsic primitives (built-in functions for generating graphics figures) supported by this program are DOT, VECTOR, RECTANGLE, CIRCLE, CONCATENATED VECTOR, Y-BAR and X-BAR. Extended primitives (those using software routines for generating the figures) demonstrated in this program are WIDE_VECTOR, SLANT_RECTANGLE, ARROW and DOUBLE-HEADED_ARROW.

The primitives, the information required to produce them and examples of results are shown in Figure 14, page 36. Note the position relationships between the coordinates and the final figures.

The plot mode, or state, must first be enabled for graphics primitives to print. When in plot mode the cursor is displayed as a blinking dot (representing the pixel location) followed by a line, "-__".

2. Character Mode

Characters entered will be displayed on the screen in the position indicated by the cursor (blinking lines indicating the top and bottom of the character position). A character position is ten dots high and six
<table>

<td>((x_1, y_1))</td>
</tr>
<tr>
<td></td>
<td>(var and fixed head options)</td>
<td>((x_2, y_2))</td>
</tr>
</tbody>
</table>

Notes: PLOT must be enabled for all primitives. R, HT and W may be input as digits or as cursor positions and "hits". Options such as BLINK, FILL, DOTTED and fixed head should be selected in advance of the primitive selection.

**FIGURE 14.**

**THE PRIMITIVES**
FIGURE 15b.
SHIFT, ALTERNATE-CHARACTER-SET
dots wide and includes inter-character and interline spacing.

Any of four display character sets of 96 characters each can easily be displayed on the terminal. (See Figures 12, 15a and 15b.) Note that Figure 12 represents two different character sets: upper case and lower case standard characters.

E. OTHER FUNCTIONS AND COMMANDS

1. **Create Buffer**

   Use of the CREATE key sets up a buffer which stores all subsequent characters used for displays as they are entered into the terminal. Multiple subbuffers (up to 255) may be created by separating the data with an end of record (EOR) character, CTRL X. Hitting the CREATE key when the light is on will terminate the function and cause the light to go out. The command "ESC K hnum" kills only a portion of the buffer: the data between EOR marks hnum and hnum + 1 is erased and the following data is compressed, leaving additional room at the end of the buffer. (hnum is always entered in HEX and can be any number from 00 to FF.)

   If it is later desired to add to the create buffer, the APPEND key may be used. Subsequent characters are added to the end of the buffer rather than at the first location. The function is terminated as above.

   The REDRAW key maps the contents of the buffer to a window, usually the full screen unless windows have been redefined. There is a command to view only a portion of the create buffer: "ESC V hnum" works like REDRAW except that only the data between EOR marks hnum and hnum + 1 is sent to the display screen.
2. **Zoom**

The ZOOM key allows the user to select any rectangular subset of the screen and enlarge it to the full window area. The original contents of the window are destroyed by this function unless CREATE and REDRAW are used to restore the old contents.

Example:

```
CREATE  ERASE  PAGE  RED  PLOT  RECT  .  
--> (key 12 right arrows)  ↓ (key 3 down arrows)
.  RETURN  ↓  ↓  -->  PLOT(off)  CYAN
C  H  R  O  M  A  T  I  C  S
HOME  CREATE(off)  ZOOM  .  --> (12 arrows)
↓ (3 arrows) .  REDRAW
```

3. **Complex Fill**

This function is useful for filling in polygons or producing special shading effects. A two-tone fill is possible by using both a background fill color for the solid portion and a foreground fill color for the pattern. Although this command is a bit complicated the effects possible are a nice addition to the capabilities of the system; it is worth some effort to understand the requirements:

- Be sure polygon border is completely closed.
- Polygon border must "contain" the foreground fill color.
- Place cursor inside polygon to be filled.
- Set background NOT black,
- Set foreground fill color for character or pattern,
- Key in "MODE > char" where char is any character.
(Or use the preprogrammed F1 through F8 keys)

If "char" is a blank, the polygon fills solidly with the background color only. To determine which colors are "contained" within another color, some experimenting may be helpful. There are three primary color planes: red, green and blue. Yellow contains red and green; magenta contains red and blue; cyan contains green and blue; white contains all three color planes. Black is the absence of any of the three color planes. (Note: the instructions for Complex Fill in Chro78b, Sect 4.1.8, are in error.) Sample Session 3 in the Appendix illustrates use of Complex Fill, and notes the importance of registering cursor position if the create buffer is used. The CURSOR X-Y function key is sometimes useful for this.

4. Windowing

The WINDOW key allows defining of up to four windows: #0, #1, #2, #3. The following key sequence defines window #0 to be the upper left quadrant of the screen and fills the window with +'s:

```
WINDOW 000 511 255 255 MODE T +
```

In order to display to other windows, they must be assigned to the appropriate logical output devices. For example:

```
WINDOW 000 511 255 255             window #0=upper left
BACKGROUND GREEN ERASE PAGE        make window visible
ESC O A 1                         set up window #1
WINDOW 256 511 511 256             window #1=upper right
MODE J                             make cursor visible
RED A B C                          write to window #1
```

Note: assigning a window does not affect the status of the lights on
the illuminated keys; therefore, the lights on the keys do not indicate the mode of the window but instead reflect the meaning of the key. Although the BACKGROUND key is illuminated in the example above, the final line does NOT set the background color to red, but rather the foreground color. Striking the BACKGROUND key will realign it with the mode of the window. To change the background color of window #1, the BACKGROUND key must be struck twice.

Continued example:

```
BACKGROUND(off) BACKGROUND RED ERASE PAGE
BACKGROUND(off) BLACK foreground w #1=black
MODE X 3, MODE Y 3, char size = 3 x 3
A B C write to window #1
```

Window #1 has now been set up with entirely different characteristics from window #0. Window #0 retains its identity as shown by the continuation of the example:

```
ESC 0 A 0 set up window #0
A B C write to it
```

The keyboard synchronization command "MODE 0" (zero), causes the status of the addressed window to be sent to the keyboard illuminated keys. After a keyboard "sync" command, the window status will be accurately reflected by the illuminated keys.

Windows may be defined to be overlapping. When two windows share the same point on the screen, whichever window writes the point last is the one that affects that point.

Continued example:

```
ESC 0 A 2 set up w #2
BACKGROUND MAGENTA ERASE PAGE color it
```
ESC 0 A 1  move back to w≠1
ERASE PAGE  note difference

The following illustration shows what happens when a window boundary is exceeded:

WINDOW . --> --> --> --> ↓ . ↓
BACKGROUND BLUE ERASE PAGE
LF --> SHIFT ↓ SHIFT ↓ SHIFT ↓ SHIFT ↓

ABCDEF

This sequence uses the cursor control to define the window. Note that the information written outside the window is not cleared by the ERASE PAGE.
III. PROGRAM INFORMATION AND POSSIBLE MODIFICATIONS

A. PROGRAM DETAILS

1. Explanation of Variables

Four different one-dimensional arrays are set up as follows:

**PS$** - This string array stores data associated with the special function keys on the upper three rows of the keyboard. The functions of each of these keys (except for the RESET key) can be duplicated from the basic keyboard using a combination of keys; therefore the upper three rows are merely a convenience for the user. The array is first initialized so that each position contains CHR$(7), the ASCII code for the "bell". Keys which need to be suppressed under program control (because they would kill the program) are then trapped and the "bell" is printed instead of the usual function. Keys which do not interfere with the program and are an advantage to the user need to be enabled; the array positions for these keys are refilled with appropriate data.

**C** - This array is used to store user input such as coordinates and other parameters for primitives like radius (for circle) or height (for slant rectangle).

**X, Y** - These two arrays are used for plotting of coordinates in the overlay routines.

A number of flags are used in this program; they are summarized in Figure 16, page 45. The last two flags in the table became necessary

**FIGURE 17.**

OVERLAY ROUTINE PARAMETERS
due to the unusual way the tablet handles input/output in stream mode. There is an apparent delay in registering the coordinate values from the tablet. After a "hit" in selecting tablet coordinates, the first coordinates gathered are not the ones desired but are instead the coordinates just previous to the ones selected. A double input statement is used to "discard" the first coordinates and store the ones actually selected.

If the user is in point mode the delay does not occur and the double input statement is unnecessary. The PM flag is TRUE and the first input statement is bypassed.

A complication occurs when moving from stream to point mode. The first time coordinates are selected in point mode after having selected coordinates in stream mode, the coordinate pair from the last "hit" is still stored and erroneously picked up as the first "hit" in point mode. The following table summarizes the action taken to avoid this undesirable selection of a point:

<table>
<thead>
<tr>
<th>OC</th>
<th>PF</th>

<tr>
<td>-1</td>
<td>-1</td>
<td>Use up old point</td>
</tr>
</tbody>
</table>

Note that in BASIC the NOT of 0 is -1, so it is necessary to use these values for logical operations involving NOT. A flag with value 0 is defined as FALSE while a flag with any other value is defined as TRUE.

Some overlay routine variables are necessary in the main driver for the passing of input data. These are detailed in Figure 17, page 46.
Tablet variables include the following:

SP$ - Speed of picking up coordinates:

"0" = stream mode, 70 coordinate pairs per second
"P" = point mode
"S" = idle mode (stop)

Other speeds are available. (See Chro79a.)

XI, YY - Used to store raw coordinates from the tablet; their range is 0 to 2200.

X1, Y1 - Used to store scaled coordinates to pass from tablet to screen.

OX, OY - Used to copy values of coordinates input so comparison can be made with next input to see if conditions have changed.

F$ - Used to store value of 4-button cursor key used:

"0" = no hit
"1" = top button hit
"2" = left button hit - unused in this program
"4" = bottom button hit
"8" = right button hit - unused in this program.

PR$ - Used as a temporary to store code for primitive selected while outputting dots for points selected in tablet stream mode.

Other variables used include the following:

K - Used to store the input from the keyboard,

LO - Used to store contents of the location in memory which keeps bit information for state conditions.

COL - Used to store contents of the location in memory which
keeps bit information for background color.

BG - Used to determine background color.

NC - Used to indicate the number of coordinates plus other variables needed as input for a primitive.

CT - Used to count the number of coordinates in digit input mode; since 3 digits = 1 coordinate, the digits are stored in array C when CT indicates 3 digits have been input.

I, M - Used as subscripts to array C when filling C and printing from C, respectively.

2. **Explanation of Code Sections**

**PART1** contains the initialization and is executed only once. The "MODEOFF" statement is used to enable reading of the keyboard directly. Mode codes are now echoed as tildes and escape codes are echoed as reverse apostrophes. Without this command a mode code would stop program execution and echo further input to the output device until the RETURN key was typed.

Logical to physical device assignments are made and initial states are set. Data, such as the color codes and primitive codes, is placed in the array P$. Part 1 then "chains" to Part 2.

**PART2** contains the main driver. The first section is the **interrupt handler**. The program loops on a statement until an interrupt is detected. If it is indeed a keyboard interrupt (ERR=24), then the input is stored. Trapping of further interrupts is disabled by the "ON ERROR GOTO 0" statement which causes BASIC to print an error message on any subsequent errors and terminate execution.

Some of the ASCII codes remain unassigned and could be used for new
input functions (see ASCII chart in Chro78b). The interrupt handler determines which key caused the interrupt (see Figure 18, page 51, for key code values) and branches to the appropriate place in the program. Some types of keyboard interrupts are disallowed during certain routines, such as coordinate gathering, to prevent nested subroutine calls from being stacked up. A "RESUME" statement reenables the keyboard interrupts.

The primitive handler section is entered if the interrupt handler detects a primitive. The number of coordinates and attributes for that primitive is set with an assignment to the variable NC. Since it is impossible to determine ahead of time how many coordinates are expected for concatenated primitives, NC is arbitrarily set at 999. This section then branches to a subroutine which fetches the desired input and returns it in array C. If the primitive is a built-in primitive, the contents of C are then output to the underlying Chromatics software with a "PLOT" statement. If the primitive is one of the extended primitives, the contents of array C are assigned to the Part 3 or Part 4 parameters and the appropriate overlay is loaded.

Concatenated primitives are again an exception: it is assumed the user would like to see the results as coordinate selection occurs and therefore these primitives are printed out as selection occurs.

At the conclusion of this section, NC is reset to zero to indicate that no coordinates are presently being sought and the full range of keyboard interrupts is enabled.

State changes are handled by accessing a fixed memory location, &H3B52, and performing a logical AND with the appropriate hexadecimal value to check bits. The condition of the state is reversed and any

**FIGURE 19.**

**SUMMARY OF MACHINE STATES**
flags are switched. The states are summarized in Figure 19, page 52.

When the tablet is first selected the code branches to a small subsection which does tablet initialization, including device assignments.

The create mode is not an initial condition; it is turned on only as a user option. The program automatically resets ROLL off and PLOT on so that these states are recorded in the create buffer. A flag is set so that it is possible to test for user request for create mode irrespective of whether the create light itself is on or off.

Many commands, such as tablet cursor movements, are not needed in recreating a display; some commands, such as the "bell", tend to be annoying when reexecuted from the buffer in a REDRAW command. These reasons in addition to space considerations provide incentive for elimination of unnecessary items from the create buffer. Therefore, the program continually turns create mode off unless the input information is necessary for a display. Since proper placement of characters depends on knowing the position of the cursor (including any backspacing to correct errors!), the cursor movements are recorded in the create buffer if character mode is on.

The end of file (EOF) character, CHR$(30), turns the create buffer off. Create mode is reenabled with ESCape "Q", which appends to the last EOF in the buffer; note that ESCape "C" or the CREATE key always begins at the first buffer position.

Background color is also stored in a fixed location in memory. A "PEEK" statement transfers the contents into COL, which is then ANDed with &H55 to check which bits are on in each of the four memory planes, and the result stored in BG. The actual background color is shown by
Figure 20, page 55. Since the use of the FILL command in an overlay routine changes the background color, it is necessary to determine and store the original color before loading the overlay. This will allow restoration of the original environment.

The coordinate subroutine gathers all coordinates. Variables are initialized. The tablet flag is checked and if on, the routine branches to handle input from the tablet. Otherwise, the routine loops waiting for keyboard input. When information comes from the keyboard it is first checked by the interrupt handler section. Any coordinates using cursor position are determined by checking NC. If NC is not equal to zero, then coordinates are being fetched. A "." is then interpreted as a "hit" instead of a period, and the present cursor position is stored in the array C. Digit coordinates are gathered a digit at a time until there are three digits and then stored in array C. (Forcing the user to input three digits is an arbitrary decision but it avoids errors such as 10, 30 being interpreted as 103.0-- if a comma is accidentally omitted.) Tablet coordinates may be gathered in either stream of point mode, but only stream mode "tracks" the cursor on the screen. This portion loops until either the number of preset coordinates is reached or the function is terminated. Selected points are recorded when F$ = 1; concatenated primitives (both dots and vectors) are terminated by "4" in F$.

B. EXPANSION OF PRIMITIVES

1. Built-in Primitives

The basic set of built-in primitives which is available on the Chromatics includes the figures listed in Figure 21, page 55. Of these, all are available within this program except for the ones indicated in Figure 21. The ARC was considered to be of lower priority than most of the other primitives and no effort is made to program in the necessary code; it would not be difficult to add it. The same is true for INCREMENTAL X-BAR and INCREMENTAL Y-BAR.

The INCREMENTAL DOT is somewhat more complicated in implementation and especially in user information; for those reasons plus anticipated low user demand it is not included in this program.

The CIRCLE command contained a flaw if cursor coordinate input was used. The first "." selected the coordinates for the center of the circle; a second "." selected the radius. Previously, the first three digits (the X coordinate) of the second point were automatically picked up as the value of the radius—generally producing results which were not what the user would have been expecting. The standard distance formula from mathematics, \( \sqrt{(X1-X2)^2 + (Y1-Y2)^2} \), is used to determine the radius, with the \((Y1-Y2)\) being divided by \(\sqrt{2}\) to adjust for the difference in X-dot and Y-dot distances.

2. Extended Primitives

The set of extended graphics primitives developed by Maxine Yee (Yee80) includes routines for SLANT_RECTANGLE, WIDE_VECTOR, ARROW, and DOUBLE-HEADED_ARROW with the latter three being available in solid or dotted line mode. (See Figure 14 for details on these primitives.) The
possibility for further software extensions is clear.

The overlay techniques used are fairly simple. The command `DOS$CHAIN filename` loads in the new file while saving all variables--with their values--from the previous file. The "chained-to" program may access these variables, write to them and leave them to again be referenced or written to by the original program file (or a new overlay) with another `DOS$CHAIN filename` command to reload (load) the next file. Any variables which need to be local to a file should therefore have unique identifiers.

Since the approach to the user interface in the overlay routines (Part3 and Part4) varied considerably from the main driver (Part2), some revision was necessary for smooth transitions.

C. TABLET SIZE AND SCALING

1. User-Defined Tablet Size

   It is possible to define a small portion of the tablet and transfer it to the full screen as an enlargement technique. The appendix contains alternate code for the "tablet initialization" section (lines 1160 to 1200) of the main driver. This alternate section uses point mode and bases scaling on the initial input coordinates with which the user defined the tablet size.

2. Scaling to Avoid Distortion

   Some effort was made to scale the square tablet to a square portion of the screen. Enlarging the Y coordinates was unsuccessful since points near the top of the tablet exceeded the 511 limit of the screen and created a "wrap-around" effect. Scaling the X coordinates by
dividing by $\sqrt{2}$ (which makes X-dot distances equal to Y-dot distances on
the screen) and adding 75 was successful except in the case of circles,
where the radius needed to be able to be taken in any direction. (The
addition of 75 to the X-coordinate allowed centering of the resulting
square area on the screen. When the X-dot distances were limited to the
same horizontal length as the corresponding vertical Y-dot distances,
there were 150 more X-dots than necessary--this excess number of dots
was divided equally between the left and right hand sides of the screen
so that the resulting area would be centered and the unused portions
would be on the edges of the screen.) Work in this area was not
considered a priority and was not pursued although a comprehensive
scaling transformation from tablet to screen coordinates would be
helpful.

D. FUNCTION KEYS

The function keys marked F1 through F8 at the upper right of the
keyboard are programmed to provide special shading effects. Functions
for these keys are stored in the P$ array. Each of these keys performs
a complex fill using an arbitrary selection from the alternate character
set (Figure 15b) as the fill character. It would be easy to make other
selections from the alternate character set or otherwise reprogram these
keys. When one of these keys is detected in the interrupt handler
section, the code plots the cursor position for window 0, shifts to the
alternate character set, prints the complex fill command, returns to the
standard character set and branches to the end of the main driver. All
that the user has to do is set the background and foreground colors as
directed in the section on complex fill.
These function keys, when not under program control, can be programmed by the user to define specific sequences of commands in the following way:

F1 F1 Fn  (where n = 2 to 8)

sequence of commands

Fn

Now, whenever the Fn key is hit, the entire sequence defined is executed. Passing these keys through the program in their original state would add to the flexibility of the program for a sophisticated user.

E. MULTIPLE WINDOWS

Although it is possible to define multiple windows within this program, there are some limitations. Statements #500 and #610 plot the cursor position from window #0 only. It would be possible to set up a variable for the window number and plot the cursor from any of the four windows.

SAMPLE SESSION 1

I. GOALS: (1) To demonstrate the built-in primitives;
(2) To demonstrate coordinate input in three modes;
(3) To demonstrate state changes;
(4) To demonstrate use of the create buffer.

II. GETTING STARTED

- Insert disk into disk drive with label side up and with label toward you, until the disk clicks and stays in place.
- Pull latch down to lock in the disk.
- Push "on" light on Chromatics and on disk drive, so that both lights appear lighted (refer to Figures 5 and 7).
- Push RESET, BOOT/WIDE VECTOR, BASIC/SLANT RECT. and RETURN. The last item on the screen should be a prompt in green which says, "OK".
- Push the reset button on the right side of the tablet to reset it to initial states (refer to Figure 9). (If you fail to do this you may get a "TYPE MISMATCH" error the first time you try to use the tablet.)
- Type DOS"LOAD PART1; push RETURN. (The machine will load the program and return with the prompt "OK".)
- Type RUN; push RETURN. (The machine will begin execution of the program and set initial conditions: the "plot key" should be lighted and all others unlighted while the cursor for plot. ".__", should appear at the upper left of the screen in home position.)
III. ENTERING COMMANDS

Push the following keys in the KEY column in the order given. The returning prompt and/or explanation is given in the MACHINE RESPONSE column. The SCREEN CHANGES, if any, are noted.

</tbody>
</table>

III. SAVING YOUR FILE

Push the BREAK key. You will get a prompt; if it is not on a new line push RETURN (ignore any "SYNTAX ERROR" messages at this point). Type `DOS"BUFF fn` where "fn" stands for filename, that is, any name you wish to give to your file. Then push RETURN. The information you stored in the create buffer should now be in the process of being stored on the disk. You can access your file at any time with the commands RESET, BOOT/WIDE VECTOR, DISK OS/DOTTED LINE, RETURN. You will get a prompt, "**". Then type `DRAW fn` (again using your unique filename). When another "**" prompt appears it means that your file is loaded into memory. Now simply push REDRAW and your selections will be recreated.
SAMPLE SESSION 2

I. GOALS: (1) To demonstrate use of point mode.
   (2) To demonstrate blink mode,
   (3) To demonstrate priority of overlapping regions,
   (4) To demonstrate "erasing" by using background color,
   (5) To demonstrate character size change,
   (6) To demonstrate positioning of characters for create buffer.

II. GETTING STARTED

   Securely fasten a copy of Figure 22b to the tablet (taping at opposite corners should be adequate). Figure 22b is an adjustment which allows for the distortion of translating tablet coordinates in a 1:1 ratio to screen coordinates in a 5:7 ratio; Figure 22a illustrates the desired result. Follow the sequence of directions given in Sample Session 1, part II.

III. ENTERING COMMANDS

   Execute the commands given in the COMMAND column in the order given. Be sure to "turn off" the concatenated figures before trying to proceed. The RESULTS and/or EXPLANATION is given for each sequence.

SAMPLE SESSION 3

I. GOALS: (1) To demonstrate use of the create buffer;

(2) To demonstrate complex fill;

(3) To demonstrate CURSOR X-Y command;

(4) To demonstrate use of alternate character set.

II. GETTING STARTED

Follow the directions from Sample Session 1 to load the program and prepare for data entry. It will probably be helpful to refer to Figure 23 when positioning the cursor.

III. ENTERING COMMANDS

Push the following keys in the KEY SEQUENCE column in the order given. The results and/or explanations are noted.

<table>
<thead>
<tr>
<th>GOAL</th>
<th>KEY SEQUENCE</th>
<th>RESULTS/EXPLANATIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>CREATE BACKGROUNDBACKGROUND BLACK BACKGROUND(off) ERASE PAGE</td>
<td>Set Create Buffer on (These 4 steps are optional; background color is picked up from machine setting prior to REDRAW in any event!)</td>
</tr>
<tr>
<td>2</td>
<td>WHITE</td>
<td>White &quot;contains&quot; all other colors and works well for Complex Fill</td>
</tr>
<tr>
<td></td>
<td>CIRCLE 128 170 030</td>
<td>White circle appears at lower left</td>
</tr>
<tr>
<td></td>
<td>CIRCLE 128 170 050</td>
<td>2nd circle around the first</td>
</tr>
<tr>
<td></td>

ABSTRACT

This report describes a system driver designed for the Chromatics CG (computer graphics) 1999. The program allows the user to extend the performance of the Chromatics in two primary areas: input capability and extension of graphics primitives.

Using Chromatics commands under program control, the interface supresses keys which would kill the program while redefining some keys for new commands.

Coordinate input for graphics primitives is accepted in any of four modes:

(1) from the keyboard as digit coordinates,
(2) from the keyboard as cursor position.
(3) from the tablet, positioning from the four-button cursor on the tablet.
(4) from the tablet, positioning from the cursor on the screen.

The program expands the set of graphics primitives available. While built-in primitives such as circles and rectangles are available on the Chromatics itself, extended primitives such as thickened lines and arrows are accessed from disk using an overlay.

A Users' Guide is provided along with sample programs and diagrams which illustrate the use of the driver. Source code and details related to programming options give opportunity for modification to suit individual applications.
