## INTRODUCTION

Adolescence is a period in life characterized by rapid changes in physical size and personality development. The growth rates at this time are exceeded only by those in utero and in the first year of postnatal life (1). The growth spurt in the average female adolescent begins around the age of ten and is usually completed by the age of 15, although there is considerable variation among girls in the time of onset and the duration of growth (1). Because of this dramatic increase in growth and development, the adolescent has a greater need for nutrients. An increased need for protein, iron, and calcium occurs with the increase in lean body mass (1). Menstruation further increases the need for iron.

The quality of the diet consumed by most teenagers has often been questioned because of the change in eating habits that usually accompanies adolescence. Some of these changes include skipping meals, snacking on low nutrient dense foods, eating away from home, and exploring alternative dietary patterns such as vegetarianism and megavitamin therapy (2). Other factors such as alcohol and drug abuse, participation in sports, and pregnancy also have the potential to alter nutritional status of this age group. Although there is individual variation, research studies indicate that the diets of adolescents, especially adolescent girls, are low in certain nutrients (3-5).

The emphasis on slimness in our society has a great impact on the girl of pubertal age. The media's portrayal of the ideal woman as being ultra-thin only compounds the problem. Many young girls often try to achieve this image by following unconventional or self-styled dietary regimens which may not be nutritionally adequate. Attempts to change

appearance through weight reduction decreases food intake, and subsequently dietary quality.

A primary need of adolescents is acceptance by their peers and "approval" strongly influences their conception of themselves (6). Body image becomes an important factor in the development of the self-concept and may affect the quality of their diets.

Because of the extreme preoccupation with diet and weight control among adolescent girls and because their diets have been found to be low in some major nutrients, studies of the effect of their self-concept on the quality of their diets are justified. The objectives of this study of adolescent girls were:

- 1) to examine their self-concept.
- 2) to estimate their total body fat (fat weight) by calculating arm fat areas.
- 3) to investigate the relationship between their self-concept and their arm fat area.
- 4) to investigate the relationship between the quality of the diet and the self-concept of a subset of the sample of girls whose self-concept and fat weight were determined.

## REVIEW OF LITERATURE

## Nutritional Assessment

## Methods of Assessment

The assessment of nutritional status is a comprehensive process aimed at identifying individuals or population groups at nutritional risk. In this process various kinds of information are collected and evaluated for use in developing nutrition education programs to help individuals and groups improve their diets. Assessment techniques include clinical evaluation, biochemical assessment, anthropometric measurements, and investigation of nutrient intake. Each of these methods has strengths and limitations and no method alone provides a complete assessment of nutritional status. The methods of assessment selected depends on the available laboratory facilities, funding, personnel, and time (7).

Anthropometric Measurements. Growth and physical development are the result of many complex biochemical functions that are dependent upon an adequate supply of nutrients. A child's pattern of growth and progress along a channel can indicate whether the diet is supplying sufficient nutrients for growth and other physiological needs without an excess that can lead to obesity.

The anthropometric measurements used most commonly include height, weight, triceps skinfold thickness, and mid-upper arm circumferences (8). At the 1968 White House Conference on Food, Nutrition, and Health (9) measurements of weight, standing height, and arm circumferences were recommended for the assessment of growth in school-age children through adolescence. Simko et al. (10) suggested weight and length as standard measurements for infants and children and triceps skinfold and arm

circumference measurements when a nutritional abnormality such as obesity or wasting is suspected. They also suggested measurements of triceps skinfold thickness and arm circumference for assessing the adequacy of lean and fat tissues in adolescents, adults, and elderly persons. Abraham et al. (11) stated that skinfold measurements can indicate the fat content of the subcutaneous tissues, which correlate well with total fat content of the body. Thus, skinfold measurements can be used to differentiate between an individual who is overweight because of muscle mass and one who is simply obese. Although there are 22 known body sites from which skinfold thicknesses may be obtained, the triceps skinfold is used most often since standards are available for the American population (12).

Dietary Intake. Investigations of dietary intake are conducted to identify those individuals who may be at risk of nutritional inadequacy. The findings are used to determine the sources and amounts of nutrients consumed and also to indicate general food patterns. Because absolute accuracy is difficult to achieve, the evaluation of dietary intake often is used in conjunction with another nutritional assessment method.

Methods of Data Collection. Dietary intake data from individuals can be obtained by several methods including the following (7, 13):

1. A 24-hour dietary recall interview in which the individual is asked to recall all foods and beverages consumed during the preceding 24 hours.
2. Records of food intake with the food expressed in weights, household measures or estimated quantities over a specified period of time.
3. A self-administered questionnaire or interview to obtain general information on the frequency of foods consumed.
4. A diet history obtained by a trained interviewer to determine the usual food intake pattern over a long period of time.
5. Laboratory studies in which duplicate samples of food are weighed and analyzed for nutrient composition.

Each method has its own strengths and weaknesses, but for most purposes researchers (12-15) agree that the 24-hour dietary recall is an effective method for dietary data collection. This method requires less time, money, subject cooperation, and professional personnel than most of the other methods (7).

As early as 1948, Bransby et al. (16) reported that 24-hour recall interviews were as accurate as weighed food records for assessing dietary intake of boys living at home or in residence halls. Data from the 24-hour recalls correlated well with food intake records kept at the halls. Young et al. (14) found that a seven-day food record was better than a 24-hour recall for analyzing the nutrient intake of one individual, but that the two methods could be used interchangeably in studies of groups of individuals. In a comparison of data from one-, seven-, 14-, and 28-day dietary records, Chalmers et al. (15) reported that the one-day record could estimate the mean intake of a group as accurately as the other three time periods. Because people tend to eat better when a one-day record is used, these researchers stated that the 24-hour recall might provide a more accurate dietary assessment.

Bosley (17) reported that 9 to 11 year-old children were able to recall their food intake during the previous 24-hours. She found this age group to be spontaneously curious, honest and more likely to answer truthfully than older children. Children in grades one through four were interviewed for recall of one day's diet in a study conducted by Emmons and Hayes (18). Measuring spoons and cups and different size servings of food were used to help the children determine the quantity of foods consumed. Mothers were then interviewed by phone for their recall of the child's diet during the same 24-hour period. Interviews were conducted

from Tuesday through Friday so that a school lunch was included in each day's meals. They found higher correlations between the nutritive levels calculated from the child's recall of lunch and lunch actually eaten than between those calculated from the recalls from the mother and from the child. The fourth graders were better able to recall correctly the foods eaten at home and school than the first graders. These researchers concluded that young children are able to recall one day's diet as accurately or more accurately than their mothers and that those above the second grade can give accurate dietary information.

**Assessment of Dietary Quality.** Traditionally, the nutrient content of recorded diets has been computed from tables of food composition and the resultant values have been compared to the appropriate Recommended Dietary Allowances (RDA) (19) or other accepted standards, such as those used with data from the Health and Nutrition Examination Survey (HANES) (20) or the Ten-State Nutrition Survey (TSNS) (21). Despite the ready availability of computers, data banks, and appropriate programs, calculations of the nutrient content of diets are tedious, time-consuming, and costly. For these reasons nutritionists have developed simpler methods, such as dietary scores, which are based on selected nutrients or food groups, for scoring dietary quality.

In 1954, Thomas et al. (22) developed and tested a method for assessing the quality of dietary intakes of 1,128 black and white women living in Detroit. The objective of their study was to determine qualitative differences in the intakes of groups of individuals and to identify extreme levels of intake rather than individual nutrient intakes. Their system was based on 14 food groups with points allotted to groups with maximum scores of 100 percent being equivalent to 125, 139, and 160 points for

non-pregnant, pregnant, and lactating women, respectively. The number of servings was set to meet the RDA for energy and eight nutrients for the three groups. This scoring system proved to be a simple and reliable method for assessing the dietary quality of women of low socioeconomic status. Later, Hinton et al. (4) used this system to investigate the relationships among psychological, sociological, and physiological factors and eating behavior of 140 adolescent girls in Iowa.

In a study of the factors affecting teenage food habits, Schorr et al. (5) used a Guttman scale or scalogram (23) to assess the quality of diets of 118 New York state seventh to twelfth grade students. The Guttman scale is cumulative, with any given scale step containing the food items therein and all those in preceding steps. This scale is often used to measure dietary complexity and is especially useful for large groups of people consuming many different food items. The study conducted by Schorr included a seven step version of the Guttman scale with the following seven food groups: whole milk, breads and rolls, beef, sweet foods and snack foods, fruits, orange juice, dark-green leafy and deep-yellow vegetables. With each succeeding scale step, the percentage of students included decreased while the level of dietary complexity increased.

Greger et al. (24) investigated the dietary intakes of 178 adolescent females from 24-hour dietary recalls collected during both the fall and spring of one school year. Two methods were used to assign dietary quality scores to each diet. One method involved summing all servings from the four food groups to give the Basic Four Total. The second method, the Modified Basic Four Total, was calculated by adding all servings from the four food groups, provided the number of servings from each group did not exceed the recommended number of servings for that group. Thus, if a girl

consumed more than the recommended number of servings from a food group, only the recommended number of servings for that food group were used for calculation rather than the actual number of servings she consumed. The maximum score possible for the Modified Basic Four Total was 14. Correlations were made between the Modified Total and Basic Four Total. The researchers concluded that because Basic Four Totals can be skewed to higher levels by consumption of large amounts of food from one food group, the Modified Total is probably a better indicator of dietary quality.

MacDonald et al. (25) also used a dietary score to assess the quality of diets of 256 Canadian girls. The Canadian Food Guide (26), which recommends four servings of milk or milk products, five servings of bread and/or cereals, five servings of fruits and/or vegetables and two servings of meat or meat alternatives per day to yield a maximum score of 16 points for adolescents, was used as a basis for the assessment. The authors stated that this guide is not intended as a standard against which dietary quality is rigorously assessed, but is useful in separating those individuals with poor food intakes from those with very good intakes. After 24-hour food records were collected from each girl, the number of servings from each food group was totaled to give a final score. On the basis of this scoring method, the 50 best (i.e., highest scores) and the 50 worst (i.e., lowest scores) diets were identified. These researchers concluded that although this scoring method is a gross estimate of dietary quality, it served to separate two very distinct groups with respect to dietary intake.

The Recommended Dietary Allowances are intended to serve as guides for achieving and maintaining adequate nutritional status. Many researchers use the RDAs as a basis for estimating the prevalence of low

dietary intakes in various population groups but caution must be used in drawing conclusions from these comparisons (27). Failure to achieve these levels of intake is not necessarily indicative of nutritional inadequacy. The United States Department of Agriculture (USDA) specified two-thirds of the RDA as the standard for identifying subjects at possible nutritional risk in the 1965-66 Household Food Consumption Survey (28).

Several different scoring systems based on the RDA have been developed for assessing nutrient adequacy. In a study of the differences in nutrient intake of high school students participating and not participating in the school lunch program, Howe and Vaden (29) used a method developed by Cospser (30) to determine dietary quality. Percentages of the RDA for protein, calcium, iron, vitamin A, thiamin, riboflavin, niacin, and ascorbic acid were calculated from 24-hour dietary recalls. Intakes equal to or greater than 100 percent of the RDA for all nutrients were classified as "excellent." If intakes were equal to or greater than 66.7 percent, they were rated as "good." The diets were rated as "fair" if intakes for all nutrients were equal to or greater than 50 percent, and "poor" if intakes were less than 50 percent of the RDA.

Schafer (31) used a similar method developed by Yetley (32) to study the effect of self-concept on the dietary quality of young married women. Intakes of protein, calcium, iron, vitamin A, thiamin, and ascorbic acid were calculated from 24-hour dietary recall interviews. Three points and an "excellent" rating were assigned to diets that met or exceeded the RDA for all six nutrients, two points and a rating of "good" to diets with 67 to 99 percent of the RDA and one point to the "poor" diets that provided less than 67 percent of the RDA.

Using percentages of the ROA as a measure of nutritional adequacy is a common practice among researchers. A percentage of the ROA for a single nutrient according to an individual's sex and age is referred to as the nutrient adequacy ratio (NAR). Madden and Yoder (33) used NAR values to evaluate the effectiveness of food distribution programs in rural Pennsylvania. NAR values can be used to compute mean adequacy ratios (MARs) which are used to judge overall dietary quality. MAR values are obtained by totaling NAR values and computing a mean value. All NAR values greater than 100 percent are truncated to 100 to prevent intakes exceeding the RDA for one nutrient compensating for inadequacies of others.

Newell et al. (34) evaluated the dietary quality of 1,242 Kansas fifth grade students by computing MAR values. Nutrient adequacy ratios were calculated for energy and nine nutrients, including and excluding supplements, from 24-hour recalls. Then, using two-thirds of the ROA as a starting point, they grouped the MAR values into four ranges as follows:

90 to 100  
75 to <90  
66 to <75  
<66

In a study of 212 university students, Guthrie and Scheer (35) compared the validity of a quality score based on the Basic Four Food Guide (36) with that of a MAR based on 12 nutrients. Using 24-hour food records, four points were assigned to each of the four food groups for a possible total score of 16 points and MARs were calculated from the percentages of the 12 ROAs. The diets that scored 16 points also provided greater than 78 percent of the ROA for all 12 nutrients investigated. Guthrie and Scheer concluded that when the objective is to evaluate program effectiveness, the simple dietary score can be substituted for the more time-consuming dietary analysis.

Regardless of the type of quality score used, there is an apparent need for a simplified method of determining the nutritional quality of recorded diets. Each of the above methods has advantages and disadvantages and the type chosen should depend on the time and personnel available. The MAR has been shown to estimate dietary quality as accurately as a score based on food groups and is easier and less time-consuming than comparing actual nutrient intakes to RDAs.

#### Dietary Studies of Adolescent Girls

In recent years many nutritionists have voiced their concern over the nutritional quality of the diets of American teenagers. The 1977-78 USDA National Food Consumption Survey (37) indicated that the average female 11 to 15 years of age had intakes that were below the Recommended Dietary Allowance for more than one mineral or vitamin. Calcium and iron intakes for 38 and 42 percent of the girls, respectively, were less than 60 percent of the RDA for those minerals. Intakes of vitamins A and C also were less than 60 percent of the RDA for this age group (23 and 15 percent, respectively). The Ten-State Nutrition Survey (TSNS) conducted in 1968-69 (21), which focused on low income groups, showed that adolescents between ten and 16 years of age had the highest incidence of unsatisfactory nutritional status of any of the groups surveyed. More than one-half of the female adolescents surveyed in the TSNS consumed less than two-thirds of the 1974 RDA for iron, calcium, and vitamin A. The 1971-74 Health and Nutrition Examination Survey (HANES) (38), which included all income groups, indicated that adolescence is a period of increased risk of iron deficiency in both males and females and that deficiency was most prevalent in the 12 to 17 year age group.

Similar findings have been reported in regional and local studies. The Guilford County Nutrition Committee in North Carolina (3) conducted 24-hour dietary recall interviews with 6200 teenagers in the seventh, ninth, tenth, and twelfth grades in 12 schools. Using six food groups (meat, milk, bread and cereals, green and yellow vegetables, ascorbic acid-rich vegetables, and other fruits and vegetables) the number of servings in each food group consumed by students was compared with those recommended in the USDA Basic Four Food Guide (36). Although two or more cups of milk were consumed by 66 percent of students, 14 percent had none. Milk intake was lowest in grades 10 and 12, in which only 57 percent of the students consumed two or more servings. Consumption of vegetables was very low for all students in all grades with 83 percent consuming no deep-green leafy or yellow vegetables and 59 percent consuming no ascorbic acid-rich vegetables. Although 64 percent of the students consumed two or more servings of fruit and other vegetables, total consumption of all fruit and vegetables was well below the desirable level. Thus, the diets of these teenagers were probably low in vitamin A, calcium, and ascorbic acid. The number of meals missed by these students increased from ten percent in the seventh grade to 25 percent in the twelfth grade. In one school, more than a third of those in the tenth grade and over half of the twelfth graders missed a meal. The number and type of snack food consumed by these students also were determined. The seventh and ninth graders selected mostly wholesome foods for snacking such as fruit, bread, and milk, whereas those in grades 10 and 12 chose soft drinks, desserts, and candy.

Schorr et al. (5) studied the food habits of 118 adolescents in grades seven through twelve. Food preferences were obtained by asking

students to indicate on a list of foods and beverages those that they "liked most," "liked least of all," and "had never tasted." Thirty-four foods received favorable responses from at least 10 percent of the students with soda pop being selected most often as the food they "liked most." Milk and steak came in second and third, respectively, and cereal was listed last. The majority of the foods in the "most disliked" list were excellent sources of vitamin A, including liver, fish, spinach, and squash.

The students also were asked to record everything they ate for three days for analysis of nutrient intake. Analysis of the 3-day food records indicated that the mean intakes of calcium, iron, ascorbic acid, and vitamin A were considerably higher for males than for females. The percentages of all students consuming less than two-thirds of the RDA for these nutrients were 21, 44, 51, and 69, respectively. The results of this study also showed that as the complexity of the diet increased so did the intakes of calcium, iron, ascorbic acid, and vitamin A. Thus, the students who consumed a wider variety of foods had more nutritious diets.

A number of studies have found the nutritional status of adolescent girls, in particular, to be less than adequate. In comparison to their male counterparts, adolescent girls often exhibit poor eating habits. Spindler and Acker (39) reported that, in general, boys have better diets than girls. Only one-fourth of the girls in this study and half of the boys consumed the recommended four cups of milk or milk substitute on the day of the recall. Less than half of both boys and girls consumed the recommended four servings of fruits and vegetables. Protein intake was adequate for 63 percent of the girls who consumed two or more servings of meat, fish, or other alternate. Bread and cereal intake was adequate for the majority of the boys but only 35 percent of the girls consumed four

servings of bread or cereal and 40 percent had fewer than three servings. Only half of the girls consumed one good source of ascorbic acid. On the day of the recall 21 percent of the girls had skipped breakfast compared to only four percent of the boys. These researchers stated that the adolescents were eager to talk about nutrition and that this information should serve as a basis for improving the current nutrition programs for adolescents.

Greger et al. (24) investigated the dietary habits of 178 female adolescents in both the fall and spring of one school year. The nutrient intake and usual meal and snack pattern were determined from 24-hour recalls and diet histories. In the fall, 20 percent of the girls ate fewer than two servings of fruits and vegetables and 18 percent consumed less than two servings of milk or milk products compared to 15 and 30 percent, respectively, in the spring. Using the Modified Basic Four Total system, 14 percent of the girls' diets were classified as poor and only four percent of the girls had diets that conformed to the Basic Four Standard (containing the recommended 14 servings).

In a study of the eating behavior and dietary intake of adolescent girls, Hinton et al. (4) analyzed 7-day food records of 140 girls between the ages of 12 and 14. The girls completed one food record in the winter and one in the summer. These researchers found that the girls consumed less milk and fewer ascorbic acid- and carotenoid-rich fruits and vegetables than are recommended for girls of this age group. Although the nutrient intake of each girl was similar from winter to summer, the winter diets tended to be more nutritionally adequate than the summer diets. They also found that the girls who consumed greater quantities of food had better quality diets than those who ate less.

As part of a four year study to identify the factors related to the body composition of adolescents, Hampton et al. (40) compared the nutrient intake of a subsample of high school students with the total sample used in the larger study. The students were asked to complete four, 7-day food records throughout a period of one year. Fifteen percent of the girls in the subsample had intakes of ascorbic acid below two-thirds of the RDA during the four periods compared to 30 percent of the girls in the total sample. Calcium and iron levels also were low with 49 and 58 percent of the girls, respectively, consuming less than two-thirds of the RDA for these nutrients. The next lowest nutrient intake was vitamin A with 15 percent of the girls receiving less than two-thirds of the recommended level. Protein intake was adequate with all subjects meeting or exceeding the RDA for that nutrient. Hampton et al. concluded that iron, calcium, and vitamin A, in that order, were the most neglected nutrients in the diets of the adolescent girls.

The vitamin B<sub>6</sub> status of 583 black and white adolescent girls was investigated by Driskell et al. (41). The mean daily intake of the vitamin was 1.2 mg as determined by coenzyme stimulation of erythrocyte alanine aminotransferase activities and two 24-hour dietary recall records. The RDA for vitamin B<sub>6</sub> is 1.8 mg/day for girls 11 to 14 years of age. The results of this study indicated that 51 percent of the girls consumed less than 70 percent and 19 percent consumed less than 50 percent of the RDA for vitamin B<sub>6</sub>.

Howe and Vaden (29) investigated the factors differentiating participants and nonparticipants in a school lunch program. Mean intakes of energy and eight nutrients were computed from 24-hour dietary recalls obtained from participants and nonparticipants. The results showed that

75.8 percent of the nonparticipating girls had diets rated as poor compared to 42 percent of the participating girls. At lunch only, more than 90 percent of the nonparticipating girls had a poor diet compared to 37 percent of the participants. The mean total day's intake of energy and all nutrients, except ascorbic acid, was significantly lower for girls than for boys. Neither participating nor nonparticipating girls met the RDA for calcium and thiamin.

#### Self-Concept of Adolescent Girls

Adolescence is a time of change in mental and emotional attributes. Probably at no other time in life is the need for acceptance by others so strong. It can be a time of confusion and uncertainty as the adolescent seeks to break the childhood ties with parents and establish a more independent lifestyle. Adolescents often become preoccupied with their own self-image and may measure their whole being solely by the reactions of their peers (42). This can lead to feelings of inferiority and a constant struggle to achieve a superficial image of perfection.

The self-concept has been defined as how a person feels about him/herself and how that person will behave in his/her environment (31). Schafer (31) postulated that people with low self-regard or self-esteem devote more energy to maintaining, defending, or building their self and are, therefore, less able to create or perform beyond the immediate emotional necessities. He further stated that a person with a good self-concept has the resources to direct attention to a higher level of involvement in secondary areas of behavior and is less likely to be influenced by others' opinions.

During early adolescence, considerable shifts in the self-concept often occur (43). Elliott (44) states that children at the age of 12 show a significant decrease in self-esteem and self-concept stability and, simultaneously, a sharp increase in depression and self-consciousness. For the female adolescent, developing a healthy self-concept is particularly difficult. Long before adolescence she has learned that physical attractiveness is a basic dimension of the female gender role (45). Acquiring an hour-glass figure consequently becomes a major task for many teenage girls. The never-ending search for beauty often leads to a negative body image, lowered self-esteem, and achievement conflicts (45).

Adolescent girls have been shown to possess lower self-esteem than adolescent boys. Stoner and Kaiser (46) used the Tennessee Self-Concept Scale (TSCS) to measure the difference in self-concept of 62 male and female high school juniors. The males scored significantly higher on three subscales: Personal Self, Social Self, and Self-Criticism. They concluded that males have a higher sense of adequacy and worth as a person and in social interactions and are more open with self-criticism than females.

Strong emphasis has been placed on the role of physical appearance in the evolution of self-concept and identity formulation (47-50). Body image appears to affect the female self-concept more than the male self-concept. Lerner and Karabenick (51) compared the body attitudes and self-concepts of 70 male and 119 female adolescents. The results indicated that mean physical attractiveness ratings were significantly related to self-concept of females but not for males. Also, the attractiveness ratings of a larger number of individual body parts were significantly related to self-concept for females than for males. Dwyer and Mayer (52)

found that physical appearance and inner self-image were more closely associated in adolescent girls than boys.

The close relationship between physical appearance and self-concept found in adolescent girls may affect food intake. Dissatisfaction with body size may lead to an alteration in diet, such as dieting (25). In a study of the factors affecting the dietary quality of adolescent girls, MacDonald et al. (25) found that the girls with the poorest diets perceived themselves to be larger than the girls with good diets and had dieted more often in the past in an attempt to reduce body weight than the girls whose diets were good. The girls with the poor diets also skipped meals more often than the girls with good diets, thus, reducing sheer quantity of food consumption. When less food is consumed, dietary quality often suffers (25). MacDonald et al. stated that the increased awareness of bodily appearance and size that occurs with adolescence coincides with a marked decrease in the quality of dietary intake.

Hinton et al. (4) studied the relationships among certain physiological, sociological, and psychological factors and eating behavior of adolescent girls. Using the Minnesota Counseling Inventory (53), they reported that girls who scored best in emotional stability, conformity, adjustment to reality, and family relationships, missed fewer meals and had better quality diets than the girls who scored less well. Analysis of 7-day food records showed a direct relationship between the quantity of food consumed and the quality of the diet. These researchers concluded that psychological adjustment is significantly related to the selection of a good diet and that eating, like other aspects of behavior, is affected by maturation and emotional adjustment.

## METHODOLOGY

### Approval and Consent

The study was conducted in a high school in a medium-sized mid-western city. Data were collected during class time on 15 year old girls enrolled in physical education classes. Approval for the study was obtained from subcommittees on research involving human subjects from the College of Education and from the Kansas State University Committee. The superintendent of the school district, principal, and physical education teachers also approved the study (Appendix A).

A letter to each parent or guardian and student that described the study and a consent form (Appendix A) were distributed in duplicate to the students by the class instructors, who also collected the completed forms. Rosters of the 160 students, who agreed to participate in the study, were developed and an identification (ID) number was assigned to each student. The first digit indicated the class and the last two digits indicated the student.

### Anthropometric Measurements

Upper arm circumference and triceps skinfold measurements were taken on all participating students. The roster of names was given to the class instructors who sent students in groups of three or four at one time to the data collection area. The measurements were taken by the investigator and recorded by an assistant on a recording form (Appendix B). Only ID numbers were used to identify students when data were recorded.

The student was asked to stand with the left arm bare and flexed 90 degrees. The midpoint between the left shoulder (tip of the acromion process) and the elbow (tip of the olecranon process) was determined and marked. Arm circumference was measured at that point with a steel measuring tape. Readings were taken to the nearest tenth of a centimeter.

Triceps skinfold measurements were taken with a skinfold caliper<sup>1</sup> at the upper arm midpoint with the arm hanging freely and relaxed. A skinfold (long axis vertical) was picked up between the thumb and forefinger and about one centimeter above the midpoint mark and directly in line with the point of the elbow or olecranon process. The caliper jaws were applied at exactly the level marked. Readings were taken to the nearest half of a millimeter. Two readings were taken on each subject; if the two readings were not the same, a third reading was taken. If three readings were required, a mean was computed for data analysis. Upper arm circumference and triceps skinfold measurements were used to estimate the arm fat area using the formula derived by Frisancho (54).

#### Self-Concept Measurement

The Tennessee Self Concept Scale (TSCS) (55) (Appendix C) was used to assess the self-concept of the participants in the study. This instrument consists of 100 self-descriptive statements to which the subject responds on a 5-point response scale ranging from "completely true" to "completely false" (56). The statements are designed to portray the different aspects of the subject's concept of himself/herself. The TSCS yields 30 scores, 29 of which have a test-retest reliability in the 0.80-0.90 range, that

---

<sup>1</sup>Lange Skinfold Caliper, Cambridge Scientific Industries, Cambridge, Maryland.

are calculated from the responses to characterize the subject's self-concept. For the present study, eleven scores of the TSCS provided measures in six general and five specific categories. The former comprised Identity (what he/she is); Self-Satisfaction (how he/she accepts him/herself); Behavior (how he/she acts); Self-Criticism (a measure of defensiveness); Total Self-Concept (overall level of self-esteem); and Total Conflict (amount of confusion concerning one's self). The five specific areas included Physical Self (view of body, state of health, physical appearance, skills, and sexuality); Moral-Ethical Self (moral worth, relationship to God, feelings of being a "good" or "bad" person, and satisfaction with religion or lack of it); Personal Self (sense of personal worth, feeling of adequacy as a person, and evaluation of personality apart from body or relationship to others); Family Self (feelings of adequacy, worth, and value as a family member); and Social Self (self as perceived in general relation to others).

The test was administered on a day when no class activities were planned. Each student was given a test booklet, answer sheet, and a pencil. Before beginning the test, the investigator announced to the students that all answers would be kept confidential and that they were not required to answer every question, however, the data would be invalid unless all questions were answered. A note with this explanation also was attached to each test booklet. After completing the test each student recorded her ID number on her answer sheet. Time to complete the test was approximately 30-40 minutes. Data from all completed answer sheets were compiled for computer scoring.

## Dietary Evaluation

### Twenty-four Hour Dietary Recall Interviews

Selection of Equipment and Materials. One dimension, life-size food models developed by the National Dairy Council were dry mounted and laminated on three 14"x22" poster boards according to food groups for use during the dietary interviews. Standard aluminum measuring cups and spoons, a 12" plastic ruler, and plastic glasses of varying sizes (5 oz., 8 oz., 10 oz., 12 oz., 16 oz., and 20 oz) were used to assist students in estimating amounts of foods eaten and beverages consumed. Each interviewer was provided with a portfolio for the food models and a plastic bag for the small equipment.

A 24-hour dietary recall form (Appendix D) was adapted from those used in related studies (57, 58). The form included space for recording the ID number of the subject, whether they took nutrient supplements or not and if so how often, and if they were presently on a special diet and why. Probing questions and procedures for interviews were modified from those used by Gilbert et al. (58) (Appendix D).

Interview Training. Training sessions with the interviewers were conducted prior to the study. The procedures to be used for the recall interviews, including a list of probing questions and visual aids were explained. Practice interviews were conducted by each interviewer prior to data collection.

Data Collection. A subsample of the 160 participating students were selected randomly for the dietary interviews. The names and ID numbers of all participating students were numbered consecutively from one to 160. Then, a random list of numbers between one and 160 were generated by computer from which the first 40 were selected. On the day of data

collection the 40 names were given to the class instructors, who dismissed the students from class for the dietary interviews.

Three interviewers conducted the dietary recall interviews at separate stations set up in teachers' offices. Each station included two folding chairs, a large desk, a set of food model posters, and a set of food measuring equipment.

#### Food Frequency

In addition to the 24-hour dietary recall, a food frequency questionnaire consisting of foods low in nutrient density was used to determine consumption of these foods on a daily, weekly, or monthly basis (Appendix D).

#### Preparation of Anthropometric, Self-Concept, and Dietary Recall Data for Statistical Analysis

The anthropometric and self-concept data were keypunched directly; prior coding was unnecessary. The data base used to develop a program to convert food intake data into nutrient values by meal was a combination of the USDA Handbook 456 (59) and the revised USDA Handbook 8-1 through 8-9 (60-68). The food composition values from these sources were merged into one data base. Food codes were assigned to the recall foods from the data base and an amount code was calculated as a multiple of the amount of food specified in the data base; i.e., if the student reported consuming one and one-half cups of milk and the nutrient analysis on the data base was for one cup quantity, the amount code entered into the computer was 1.50. Other nutrient values for food items were obtained from a previous study conducted at Kansas State University (58).

Supplements were coded as a separate meal to permit analysis of nutrient intake by meal and for the total day with or without supplements. A list of supplements was added to the data base. Since students interviewed frequently were not aware of the brand, the value of a standard supplement<sup>1</sup> was used for recording the nutrients consumed unless a specific type or brand was reported.

#### Data Analysis

Standard statistical procedures (69) were followed to analyze the anthropometric and self-concept data. Means, standard errors, and coefficients of variation were computed for arm circumference and triceps skinfold measurements and fat areas. Percentiles also were computed.

From the self-concept data, scores were calculated for each of the following: Identity, Self-Satisfaction, Behavior, Total Self-Concept, Total Conflict, Self-Criticism, Physical Self, Personal Self, Family Self, Social Self, Moral-Ethical Self, and Self-Criticism. Means standard errors, and coefficients of variation were computed for each score.

Similar procedures (69) were used to analyze energy and nutrient intakes of the adolescent girls who were interviewed, for the total day (with and without supplements) and for breakfast, lunch, dinner, and snacks. In between meal snacks were combined and reported as a meal. Means, standard errors, and coefficients of variation were computed for energy and 11 nutrients (protein, vitamin A, ascorbic acid, thiamin, riboflavin, niacin, vitamin B<sub>6</sub>, calcium, phosphorus, magnesium, and iron). Percentages of the RDA were computed for energy and 11 nutrients, as well

---

<sup>1</sup>Miles Laboratory, "One A Day" brand.

as the percentages of carbohydrate, protein, and fat in the total day's energy intake. Consumption of each of the low nutrient density foods on the food frequency questionnaire was converted to a per month basis. For statistical analysis, the list of foods was collapsed into the following groups: carbonated beverages, candy, baked desserts, and salty snacks.

To evaluate overall quality of the 24-hour dietary recalls, mean adequacy ratios (MARs) (33) were calculated. MAR values were generated by totaling nutrient adequacy ratios (NARs) and computing a mean value. Nutrient adequacy ratio refers to the percentage of the RDA for a single nutrient. All NAR values greater than 100 percent were truncated to 100 to prevent intakes in excess of the RDA for one nutrient compensating for inadequacies of others. The MAR values were obtained by using the following equation:

$$\text{MAR} = \frac{\sum_{i=1}^k X_i}{k} \text{ where } X_i = \begin{cases} \text{NAR} & \text{if NAR} \leq 100 \\ 100 & \text{if NAR} > 100 \end{cases}$$

Two MAR values, with and without supplements, were calculated. The MAR values were grouped into four ranges as follows:

90 to 100  
75 to <90  
66 to <75  
<66

Because two-thirds of the RDA has been used routinely in group assessment for signifying nutrient adequacy that value was used as a starting point for establishing ranges of MAR values.

Pearson's product-moment correlation coefficients were calculated among the MAR values; the fat areas; the self-concept scores; and consumption of the four groups of low nutrient dense foods. A stepwise regression procedure was used to examine the effect of the self-concept

scores and consumption of groups of low nutrient dense foods on MAR values, with and without supplements. A significance level of 0.50 was the criterion for the inclusion of the score or food group in the statistical model. A score or food group entered the model according to its relative contribution to the MAR value. The score or food group was subsequently eliminated from the model if after the introduction of other scores or food groups it no longer made an important contribution to the MAR index.

## RESULTS AND DISCUSSION

## Anthropometric Measurements

Means, standard deviations, selected percentiles, and coefficients of variation for the anthropometric measurements are listed in Table 1. In Table 2, selected percentiles for upper limb fat of the subjects in our study and those in the NHANES I survey (54) are compared.

At the 5th, 50th, and 95th percentile, Kansas girls had larger arm circumferences, triceps skinfolds, and arm fat areas than girls in the national survey. The arm circumference values of Kansas girls were slightly higher at each percentile than those of their national counterparts, but at the 5th and 50th percentile triceps skinfold and fat area values were twice those of girls in the national survey. At the 95th percentile, arm fat areas of Kansas girls were closer to their national counterparts than at the 5th or 50th percentile. In a 1980 study of Kansas fifth graders (70), girls also tended to have larger triceps skinfold and arm fat measurements than those in the same age group in the NHANES I study. Recent studies have indicated that fat areas are systematically better estimators of fat weight than skinfold thickness (71). For this reason, Frisancho (55) has recommended that assessment of nutritional status during growth and adulthood be made with reference to fat and muscle areas.

Dwyer et al. (72) investigated the physical characteristics of 446 female adolescents designated as either dieters or nondieters. The mean triceps skinfold measurement for both groups (21 and 15 mm, respectively) was smaller than that found in our study (28 mm). The mean arm circumference value for the dieters was identical to that of our girls (262 mm)

\*Source: Frisancho (54).

but the mean value for the nondieters was slightly lower (233 mm). Dwyer et al. did not measure arm fat area so a comparison with our girls cannot be made.

#### Self-Concept Measurement

Means and standard deviations for scores in each of the eleven categories of the Tennessee Self Concept Scale (TSCS) (55) for Kansas adolescent girls and 50th percentile norms established for TSCS are listed in Table 3. The standardization group from which the norms were developed was a broad sample of 626 people, with equal numbers of blacks and whites, males and females, between the ages of 12 and 68 (56).

Mean scores for all categories except Self-Criticism and Total Conflict fell more than one standard deviation below the 50th percentile, indicating that Kansas girls have low self-concepts. The mean Self-Criticism score was slightly above the 50th percentile, which suggests that Kansas girls were as open to self-criticism as half of those in the standardization population. The mean Total Conflict score (64.86) was higher than that for the standardization group (30.10). High scores in this category reflect confusion, contradiction, and general conflict in self-perception (56).

In terms of content areas of self-concept, mean scores for Physical Self, Moral-Ethical Self, Personal Self, Family Self, and Social Self were more than one standard deviation below the 50th percentile. A low score for Physical Self reflects a poor opinion of one's physical appearance, a finding not uncommon among teenage girls (45). The low mean Moral-Ethical score may indicate that these girls were not content with their morality or their relationship with God (56). The mean score for Personal

Table 3. Means and standard deviations for Tennessee Self Concept Scale scores for Kansas adolescent girls and 50th percentile norms from standardization group\*

| variable           | Kansas girls   | 50th percentile norms |
|--------------------|----------------|-----------------------|
| Physical Self      | 56.87 ± 4.39   | 71.78 ± 7.67          |
| Moral-Ethical Self | 54.30 ± 5.08   | 70.33 ± 8.70          |
| Personal Self      | 51.12 ± 4.34   | 64.55 ± 7.41          |
| Family Self        | 56.43 ± 5.66   | 70.83 ± 8.43          |
| Social Self        | 52.23 ± 3.99   | 68.14 ± 7.86          |
| Identity           | 82.81 ± 5.63   | 127.10 ± 9.96         |
| Self-Satisfaction  | 92.51 ± 8.18   | 103.67 ± 13.79        |
| Behavior           | 95.63 ± 6.73   | 115.01 ± 11.22        |
| Total Self-Concept | 270.96 ± 15.02 | 345.57 ± 30.70        |
| Total Conflict     | 64.86 ± 15.00  | 30.10 ± 8.21          |
| Self-Criticism     | 37.34 ± 4.48   | 35.54 ± 6.70          |

\*Source: Fitts, W.H.: Tennessee Self Concept Scale (Manual). Nashville: Counselor Recordings and Tests, 1965.

Self was the lowest of the five content areas, suggesting that Kansas girls may lack, or have yet to develop, a sense of personal worth. Family Self and Social Self scores were slightly higher than Personal Self scores but were still below the 50th percentile, indicating that these girls may feel unworthy as a family member and in social interactions with other people in general.

The Total Self-Concept score was well below the 50th percentile. A low Total Self-Concept score reflects negative feelings and behaviors concerning the self and indicates lower self-esteem.

Our findings are similar to those of other researchers. Stoner and Kaiser (46) used the TSCS to measure the self-concept of 62 adolescent girls and boys. The girls' scores were nearly identical to those found in the present study. The boys scored significantly higher than the girls on three of the subscales: Personal Self, Social Self, and Self-Criticism. These researchers concluded that adolescent girls have a lower sense of adequacy and worth as a person and in social interactions and are less open to self-criticism than adolescent boys.

The self-concept of Kansas delinquent and nondelinquent adolescent boys was measured by the TSCS in a study by Jurich and Andrews (73). Scores for the delinquent boys were similar to those of the girls in the present study and were much lower than those of the nondelinquent boys. Perhaps the girls in the present study were more concerned with their feelings and behaviors than the nondelinquent boys or they were more truthful in their responses to questions on the TSCS instrument.

Adolescence is a critical time in the development of the self-concept and low self-concept scores can be expected for this age group (74). Elliott (44) states that adolescence is a time of great disturbance in

self-concept development. Their confusion as to who they are and how they feel about themselves is reflected in the high Total Conflict score and low Total Self-Concept score. Low scores for Physical Self on the TSCS are also not uncommon with this age group. Many adolescent girls want their physical appearance to resemble that of fashion models or actresses and become disillusioned if their expectations are unfulfilled. Lerner and Karabenick (51) reported that physical attractiveness was significantly related to the self-concept of female adolescents but not of male adolescents. Similarly, Moral-Ethical scores tend to be low for the adolescent girl. The development of sexuality during this time may lead her to question her own desires; she may wonder if she is a "good" or "bad" person (74). A once stable relationship with God may now be in a state of flux (74). At this age, the adolescent girl has not yet developed a true concept of herself and may feel inferior as a person and in social interactions (74). In a study of the various dimensions of the adolescent self-concept, Elliott (44) stated that a low self-esteem leads directly to increased social anxiety. Family relationships are often strained at this time also. Hence, scores on the TSCS for Personal Self, Family Self, and Social Self are often low for adolescent girls.

#### Twenty-four Hour Dietary Recall Interviews

##### Percentage of Students Consuming and Not Consuming Meals

The percentages of students consuming breakfast, lunch, dinner, snacks, and supplements on the day of the 24-hour dietary recall are listed in Table 4. At least 80 percent of the students consumed breakfast, lunch, and dinner. Slightly more than a fourth of the students took a vitamin or mineral supplement on the day of the recall. Similar to the

findings in other dietary studies of adolescent girls, breakfast was the meal most often omitted. Spindler and Acker (39) found 21 percent of the girls in their study had skipped breakfast. Hodges and Krehl (75) reported that many of their subjects were breakfast-skippers, a habit which was associated with low ascorbic acid intake. Hinton et al. (4) reported a high correlation between the percentages of meals missed by girls and poor diets.

Table 4. Percentage of students (N = 40) consuming breakfast, lunch, dinner, snacks, and supplements on day of 24-hour dietary recall interview

|             | those consuming |   | those not consuming |   |
|-------------|-----------------|---|---------------------|---|
|             |                 | % |                     | % |
| breakfast   | 80              |   | 20                  |   |
| lunch       | 88              |   | 12                  |   |
| dinner      | 92              |   | 8                   |   |
| snacks      | 85              |   | 15                  |   |
| supplements | 28              |   | 72                  |   |

In the present study, most of the girls (85 percent) reported consuming at least one snack on the day of the recall. Eating between meals is common for many people, but especially so for teenagers. Data from the Ten-State Nutrition Survey (21) indicated that 78 percent of the teenagers interviewed ate between meals. Howe and Vaden (29) reported that between 22 and 45 percent of the total day's nutrient intake of teenagers came from between-meal snacks. Some studies have shown that snacking improved the nutritional quality of adolescent diets (76), especially those of adolescent girls (77).

### Energy and Nutrient Intakes

The means, standard deviations, and coefficients of variation for energy and nutrient intakes for the total day (with and without supplements) and from breakfast, lunch, dinner, and snacks are listed in Tables 5 and 6, respectively. Intakes of vitamin A, niacin, vitamin B<sub>6</sub>, and calcium were increased when supplements were taken by the students (Table 5). Energy, protein, vitamin A, calcium, phosphorus, and magnesium intakes were greater at lunch and dinner than at breakfast (Table 6). Snacks provided more energy, protein, phosphorus, and magnesium than breakfast and more energy, thiamin, phosphorus, and iron than lunch. Vitamin B<sub>6</sub> was supplied equally by all three meals and snacks.

### Percentages of the RDAs

The Recommended Dietary Allowances for adolescent girls, 15 through 18 years, are listed in Table 7 and were used for converting students' intakes into percentages of the RDAs. The means, standard deviations, and coefficients of variation for percentages of RDAs for the total day's energy and nutrient intake (with and without supplements) are listed in Table 8.

The students' intakes of energy, protein, ascorbic acid, thiamin, riboflavin, niacin, and phosphorus met or exceeded the RDA, with or without supplements, on the day of the recall. Vitamin A intakes increased, from 94 percent to 122 percent, when a supplement was taken. Protein and ascorbic acid intakes, 172.8 and 217.1 percent, respectively, were more than three times the RDA for those nutrients. Percentages of the RDA for thiamin and riboflavin were similar (131.65 and 135.87 percent, respectively). Vitamin B<sub>6</sub> intake increased with the addition of a supplement, from 14.8 percent to 37.3 percent of the RDA. Without supplementation,

Table 5. Means, standard deviations, and coefficients of variation of total day's energy and nutrient intake (with and without supplements) of adolescent girls (N = 40) from 24-hour dietary recall interviews

|                             | total day's meals<br>(without supplements) |                       |                                  | total day's meals<br>(with supplements) |                       |                                  |

| iron, mg                    | 78.32                                      | 46.88                 | 60                          | 80.82                                   | 49.72                 | 62                          |

this nutrient was the least adequately consumed by the students. The students almost met their RDA for calcium both with and without supplements (89 and 91 percent, respectively). Magnesium and vitamin B<sub>6</sub> intakes were less than 25 percent of their respective RDAs. Lack of food nutrient composition data for vitamin B<sub>6</sub> and magnesium probably contributed to the low values. Iron intakes were slightly more than three-fourths of the RDA.

Calcium and iron intakes of Kansas girls were higher than those reported in the 1977-78 National Food Consumption Survey (37). Mean intakes of calcium and iron for Kansas girls were about 90 and 80 percent of the RDA, respectively, without or with supplements. Over one-third of their counterparts in the national survey consumed less than 60 percent of the RDA for calcium and iron. Similarly, vitamins A and C intakes of Kansas girls exceeded those of girls in the national survey.

Energy and protein intakes of Kansas girls were similar to those of adolescent girls in other studies. Daniel (78) reported that the energy intake of girls 12 to 17 years of age ranged from 1950 kcal to 2500 kcal, and protein intakes exceeded the RDA. Energy and protein intakes decreased with age.

Four seven-day food records collected by Hampton et al. (40) showed that the protein intake of teenage girls exceeded the RDA by at least 163 percent. Although 15 percent of their girls consumed less than two-thirds the RDA for vitamin A, 49 percent had intakes exceeding the RDA for this vitamin. Calcium intakes were low with 49 percent of the girls consuming less than two-thirds of the RDA. The mean intake of calcium was 897 mg. The girls in our study consumed an average of 1065.7 mg which is much closer to the RDA of 1200 mg. Hampton et al. also reported adequate amounts of ascorbic acid for 49 percent of their subjects, however, 35

percent consumed only two-thirds of the recommended level. Iron intakes were 53 percent of the RDA compared to 78 percent (without supplements) in our study.

Vitamin B<sub>6</sub> intake was extremely low for the girls in our study. Driskell et al. (41) reported that of 583 adolescent girls interviewed, about half consumed less than 66 percent of the RDA for vitamin B<sub>6</sub>. Coenzyme stimulation values indicated that thirteen percent of the girls were of deficient status and 20 percent were considered marginal status. The girls in our study consumed an average of 0.3 mg of vitamin B<sub>6</sub> (without a supplement) and 0.7 mg (with a supplement) which is only 14.8 and 37.3 percent of the RDA, respectively.

#### Evaluation of Dietary Quality

Means, standard deviations and coefficients of variation for percentage carbohydrate, protein, and fat in total day's energy intake are listed in Table 9. The percentages for the protein and fat intakes were slightly higher and the carbohydrate slightly lower than those suggested in the second edition of the Dietary Goals (79).

Table 9. Means, standard deviations, and coefficients of variation for percent carbohydrate, protein, and fat in total day's energy intake of adolescent girls (N = 40)

|              | mean | standard<br>deviation | coefficient<br>of variation |
|--------------|------|-----------------------|-----------------------------|
|              |      |                       | %                           |
| carbohydrate | 50.1 | 12.0                  | 24                          |
| protein      | 14.5 | 4.2                   | 29                          |
| fat          | 35.4 | 10.1                  | 29                          |

Means, standard deviations, and coefficients of variation of Mean Adequacy Ratios (MARs), with and without supplements, and the percentages of subjects in selected MAR ranges are listed in Tables 10 and 11, respectively. The mean MAR value for girls who included a nutrient supplement on the recall day was only slightly higher (3 percent) than the value for those who did not take a supplement (Table 10). Although the MAR values for girls not taking a supplement were greater than 75 percent, 37 percent had MARs that were less than 66 percent. None of the students who did not take a supplement had MARs greater than 90. Supplementation increased the percentage of subjects in the 75 to less than 90 range by only one percent and decreased the percentage of those in the lower two ranges. Five percent of those who took a supplement achieved a MAR greater than 90.

Table 10. Means, standard deviations, and coefficients of variation of Mean Adequacy Ratios (MARs), without and with supplements, for adolescent girls (N = 40) from 24-hour dietary recall interviews

|                         | mean | standard deviation | coefficient of variation |
|-------------------------|------|--------------------|--------------------------|
|                         |      |                    | %                        |
| MAR, without supplement | 69   | 15                 | 22                       |
| MAR, with supplement    | 72   | 16                 | 23                       |

Table 11. Percentages of adolescent girls (N = 40) in selected ranges of Mean Adequacy Ratios (MARs)

|                         | <66 | 66 to <75 | 75 to <90 | 90 to 100 |
|-------------------------|-----|-----------|-----------|-----------|
| MAR, without supplement | 37  | 22        | 44        | 0         |
| MAR, with supplement    | 32  | 18        | 45        | 5         |

In a study of the factors differentiating participants and non-participants of the National School Lunch Program, Howe and Vaden (29) reported that 75.8 percent of the female nonparticipants had diets classified as "poor" compared to 42.1 percent of participants. Only five percent of the participants and none of the nonparticipants had diets rated as "excellent." The addition of a vitamin supplement did not improve the diet ratings of the female subjects.

Greger et al. (24) studied the dietary habits of 178 adolescent females and found their diets to be low in fruits, vegetables, and milk. The majority of girls in their study consumed less than the recommended number of servings for three of the four food groups.

MacDonald (25) investigated the nutritional quality of 24-hour dietary intakes of adolescent girls. They found that students with "good" diets consumed more food and more kilocalories from each food group than girls with "poor" diets.

In a study of food consumption and quality of diets of Kansas elementary students, between 10.5 and 12.0 years, Newell et al. (34) found that 15 percent of the girls who did not take a supplement had MARs in the  $\geq 90$ -100 range and only seven percent in the  $< 66$  range. The percentages were similar for girls who had a supplement on the recall day. The lower MAR values in our study of adolescent girls suggests a deterioration of dietary quality during adolescence or the scores may have been lowered by the incomplete values for vitamin B<sub>6</sub> and magnesium contents of food in the nutrient data base.

## Interrelationships Among the Variables

## Effect of Self-Concept Scores and Consumption of Low Nutrient Density Foods on MAR Values

Partial regression coefficients and standard errors from analysis of the effects of self-concept and consumption of low nutrient density foods on quality of diets of adolescent girls are listed in Table 12. Significant variables affecting MAR calculated without supplements were Self-Satisfaction and baked desserts. The significant variables affecting MAR with supplements were Self-Satisfaction and baked desserts. No other variables for either MAR value were significant at the  $P = 0.50$  level.

## Correlations Among the MAR Values, Fat Areas, Self-Concept Scores and Consumption of Low Nutrient Density Foods

Correlation coefficients of mean adequacy ratios (MARs) (with supplements) with anthropometric measurements, self-concept scores, and snacks of adolescent girls are listed in Table 13. MAR values were correlated negatively with carbonated beverages, candy, and baked desserts. That is, as the consumption of those foods increased the quality of the diet decreased. Fat area values were associated negatively with Physical Self and candy. The decreased consumption of candy by girls with larger fat area values may have been attributable to their reluctance to report candy consumption or they may have consumed less candy in efforts to reduce body weight. There was a positive correlation between MAR values and Self-Satisfaction. The explanation for the positive association between Family Self and carbonated beverage consumption is unclear.

The negative correlation between fat area and Physical Self in our study is similar to the finding of Hendry and Gillies (80). These researchers investigated various characteristics of 1000 15 to 16 year old

Table 12. Partial regression coefficients and standard errors from analysis of the effects of self-concept and consumption of low nutrient density foods on the quality of diets of adolescent girls from 24-hour dietary recall interviews

| variable          | MAR (without supplement) |           |        | MAR (with supplement) |           |        |

| self-satisfaction | 0.328 |          |                      |        |                |
| physical self     |       | -0.330   |                      |        |                |
| family self       |       |          | 0.390                |        |                |

\*All coefficients are significant at  $P < 0.05$ .

students categorized as "overweight," "underweight," or "average." The overweight girls possessed lower body esteem than the underweight or average girls. MacDonald et al. (25) reported that overweight adolescent girls perceived themselves to be larger than the normal weight girls which apparently led to dissatisfaction with their appearance. Research by Stunkard and Mendelson (81) indicated that two behavioral disturbances are associated with adolescent obesity: overeating and distortions of body image characterized by a feeling that the body is grotesque or should be regarded with contempt.

The positive correlation between Self-Satisfaction and MAR value in our study also is supported by other studies. MacDonald et al. (25) investigated the factors that differentiated adolescent girls with poor diets from those with good dietary intakes. They found that the girls who were less satisfied with their appearance favored skipping meals as a method of weight reduction and had diets classified as "poor." In a study of the

eating behavior of adolescent girls, Hinton et al. (4) reported that the girls who scored best in emotional stability, conformity, adjustment to reality, and family relationships, missed fewer meals and had better diets than girls with lower scores.

Schafer (31) found the self-concept to be an important factor in the quality of diets of young married women. Women who had a good self-concept tended to have better quality diets. Schafer stated that persons with a positive self-concept are likely to be confident in their abilities to select foods and prepare meals and are less dependent on others for information concerning their diet.

## SUMMARY

Adolescence is characterized by intense mental and physical growth. Many believe it is the time when the self-concept is developed and solidified. Physical appearance reportedly has a great effect on the self-concept of the adolescent female. The desire to be thin may lead to poor eating habits, such as skipping meals and following fad diets. Thus, the quality of their diets may be affected by their self-perception. Because of the paucity of information on the relationship between self-concept and dietary quality, this study was designed to investigate the effect of self-concept on the quality of diets of adolescent girls.

Scores for self-concept, measured by the Tennessee Self-Concept Scale (TSCS), and fat area values, calculated from anthropometric measurements, were obtained on 160 15 year old girls enrolled in physical education classes. A questionnaire was used to determine the frequency of consumption of low nutrient density foods, and 24-hour dietary recall interviews were conducted with a random subsample of 40 girls. Dietary data were analyzed for energy and 11 nutrients and expressed as percentages of the Recommended Dietary Allowances (RDA). Mean adequacy ratios (MARs) were calculated to assess dietary quality. Relationships among all variables were determined.

At the 5th, 50th, and 95th percentile, Kansas girls had larger arm circumferences, triceps skinfolds, and arm fat areas than their national counterparts. Their self-concept scores on most of the 11 categories of the TSCS were below the 50th percentile norms. Intakes of energy, protein, ascorbic acid, thiamin, riboflavin, niacin, and phosphorus met or exceeded the RDAs for these nutrients. Calcium, iron, magnesium, and vitamin B<sub>6</sub> intakes were less than their respective RDAs. Less than half of the girls

received MAR values greater than 75 percent and more than a third had MARs that were less than 66 percent.

MAR values were correlated negatively with carbonated beverages, candy, and baked desserts. Negative correlations also were found between fat area values and Physical Self scores. Self-Satisfaction scores were correlated positively with MAR values as were Family Self scores and carbonated beverages. Partial regression analysis showed that Self-Satisfaction and baked desserts affected MAR values significantly.

## ACKNOWLEDGMENTS

Sincere appreciation and thanks are expressed to Dr. Kathleen Newell, major professor, for her guidance and professionalism as well as her time and efforts generously given toward the completion of this project. Gratitude is also expressed to all the students and school personnel at Manhattan High School for giving their time and cooperation to make this study possible.

Appreciation is extended to Dr. Anthony Jurich, Department of Human Development and Family Studies, for his time and help with the self-concept instrument and interpretation of the data. Special recognition is extended to Nedra Sylvis for her patience and help in typing this thesis.

Gratitude is also expressed to Dr. Dallas Johnson, Department of Statistics, for his help with designing the study and also with the statistical analysis and data interpretation. Appreciation is extended to Chuck Kincaid, graduate student, for his help with the computer analysis of data.

TO: Dr. Kathleen Newell  
Foods and Nutrition  
Justin Hall

Proposal Number: 441

FROM: Robert P. Lowman, Chair  
Committee on Research Involving Human Subjects

DATE: October 23, 1984

RE: Committee Review of Your Proposal Titled The Self-Concept  
as a Factor in the Quality of Diets of Adolescent Girls  
(approved at the meeting of October 4, 1984)

The Committee on Research Involving Human Subjects has reviewed your proposal and has approved it with the stipulations indicated below and has determined that:

- There is no more than minimal risk to subjects.  
 There is greater than minimal risk to subjects.

This approval applies to this project only and only under the conditions and procedures described in the application. Any change in the protocol or conditions described in the proposal will require separate approval. This approval may be followed by a periodic review of the project and examination of records related to the project. Individual identification of human subjects in any publication is an "invasion of privacy" and requires a separately executed "informed consent."

Prior to involving human subjects, properly executed informed consent must be obtained from each subject or an authorized representative, and such forms must be retained on file for a minimum of three years after termination of the project. Each research subject must be furnished with a copy of the informed consent document for his or her personal records.

Any unanticipated problems involving risk to human subjects or others must be reported immediately to the Director of the Student Health Center and the Chairperson of the Committee on Research Involving Human Subjects.

**Stipulations:** Require spoken and written reiteration of subjects' right to withdraw or skip questions but to emphasize to subjects that if they participate the results will be invalid unless all questions are answered. This written notification should be in the form of a note attached to the front of the personality inventory and the person administering the questionnaire should remind participants verbally when they begin completing the questionnaire.

## College of Education

Office of the Dean  
Bluemont Hall  
Manhattan, Kansas 66506

December 5, 1984

Dr. Hal Rowe, Superintendent  
Unified School District 383  
2031 Poyntz  
Manhattan, KS 66502

Dear Dr. Rowe:

In keeping with the agreement between the Manhattan Public Schools and the College of Education, we have screened the enclosed proposals by Dr. Kathleen Newell and Ms. Cindy Byfield to conduct research in the schools, and are forwarding it to you for your action. The proposals have been approved by our Committee on Research Involving Human Subjects and we see no harm arising as a result of the studies.

Sincerely,

David R. Byrne, Dean  
College of Education

Dear Parent or Guardian and Student:

Your school has been selected to take part in a study of adolescent food habits. The Department of Foods and Nutrition at Kansas State University will conduct the study. The superintendent of your school district and the school principal have approved the study.

The procedures to be used in the study will be pilot tested on a random sample of 14 year old girls who are currently enrolled in physical education classes. They will be asked to complete a questionnaire concerning their self-concept, which will require about 50 minutes. In addition, arm measurements will be taken on each pilot study participant and each one will be interviewed for recall of one day's diet. The arm measurements will require about five minutes and the diet interview between 20 and 30 minutes.

Risks to the student will be minimal and all information will be kept confidential with responses and data identified by number only. We hope that all students will take part in the study, however participation is voluntary. The student may refuse to participate or discontinue participation at any time with no penalty or loss of benefits to which the student is otherwise entitled.

Data from this study will provide greater understanding of factors affecting food habits of adolescent girls that can lead to improvement in their nutritional status.

Please indicate your willingness to take part in the study on the form on the backside of this letter and return one copy to the classroom teacher tomorrow or as soon as possible. You may retain the second copy for your file. If you have any questions regarding the research, please contact Dr. Kathleen Newell (913-532-5508). Thank you for your cooperation.

Sincerely,

*Cindy Szyfield*

Dear Parent or Guardian and Student:

Your school has been selected to take part in a study of adolescent food habits. The Department of Foods and Nutrition at Kansas State University will conduct the study. The superintendent of your school district and the school principal have approved the study.

All 15 and 16 year old girls enrolled in physical education classes will be asked to participate. Each girl will be asked to complete a questionnaire concerning her self-concept, which will require about 50 minutes. In addition, arm measurements will be taken on each study participant and each one will be interviewed for recall of one day's diet. The arm measurements will require about five minutes and the diet interview between 20 and 30 minutes.

Risks to the student will be minimal and all information will be kept confidential with responses and data identified by number only. We hope that all students will take part in the study; however participation is voluntary. The student may refuse to participate or discontinue participation at any time with no penalty or loss of benefits to which the student is otherwise entitled.

Data from this study will provide greater understanding of factors affecting food habits of adolescent girls that can lead to improvement in their nutritional status.

Please indicate your willingness to take part in the study on the form on the backside of this letter and return one copy to the classroom teacher tomorrow or as soon as possible. You may retain the second copy for your file. If you have any questions regarding the research, please contact Dr. Kathleen Newell (913-532-5508). Thank you for your cooperation.

| 66. I should love my family more .....  | 66       |
| 80. I am satisfied with the way I treat other people .....                                  | 80       |
| 82. I should be more polite to others .....   | 82       |
| 84. I ought to get along better with other people .....                                     | 84       |
| 96. I gossip a little at times .....  | 96       |
| 98. At times I feel like swearing .....   | 98       |

| Completely False | Mostly False | Partly False and Partly True | Mostly True | Completely True |
|------------------|--------------|------------------------------|-------------|-----------------|
| 1                | 2            | 3                            | 4           | 5               |

|  | Item No. |
|--|----------|
| 13. I take good care of myself physically .....                              | 13       |
| 15. I try to be careful about my appearance .....                            | 15       |
| 17. I often act like I am "all thumbs" .....                                 | 17       |
| 31. I am true to my religion in my everyday life .....                       | 31       |
| 33. I try to change when I know I'm doing things that are wrong .....        | 33       |
| 35. I sometimes do very bad things .....                                     | 35       |
| 49. I can always take care of myself in any situation .....                  | 49       |
| 51. I take the blame for things without getting mad .....                    | 51       |
| 53. I do things without thinking about them first .....                      | 53       |
| 67. I try to play fair with my friends and family .....                      | 67       |
| 69. I take a real interest in my family .....                                | 69       |
| 71. I give in to my parents (Use past tense if parents are not living) ..... | 71       |
| 85. I try to understand the other fellow's point of view .....               | 85       |
| 87. I get along well with other people .....                                 | 87       |
| 89. I do not forgive others easily .....                                     | 89       |
| 99. I would rather win than lose in a game .....                             | 99       |

| Completely False | Mostly False | Partly False and Partly True | Mostly True | Completely True |
|------------------|--------------|------------------------------|-------------|-----------------|
| 1                | 2            | 3                            | 4           | 5               |

|  | Item No. |
|--|----------|
| 14. I feel good most of the time .....                                       | 14       |
| 16. I do poorly in sports and games .....                                    | 16       |
| 18. I am a poor sleeper .....  | 18       |
| 32. I do what is right most of the time .....                                | 32       |
| 34. I sometimes use unfair means to get ahead .....                          | 34       |
| 36. I have trouble doing the things that are right .....                     | 36       |
| 50. I solve my problems quite easily .....                                   | 50       |
| 52. I change my mind a lot .....   | 52       |
| 54. I try to run away from my problems .....                                 | 54       |
| 68. I do my share of work at home .....                                      | 68       |
| 70. I quarrel with my family .....   | 70       |
| 72. I do not act like my family thinks I should .....                        | 72       |
| 86. I see good points in all the people I meet .....                         | 86       |
| 88. I do not feel at ease with other people .....                            | 88       |
| 90. I find it hard to talk with strangers .....                              | 90       |
| 100. Once in a while I put off until tomorrow what I ought to do today ..... | 100      |

APPENDIX D

Procedures and Forms for Dietary  
Recall Interviews

## GUIDELINES FOR DIETARY RECALL INTERVIEWS

The objective of this study is to determine the effect the self-concept may have on the quality of diet in adolescent girls. The 24-hour dietary recall is a fact-finding mission from which we will base this comparison.

An important part of a successful interviewing technique is identifying potential sources of bias and overcoming as many of these sources as possible prior to the interview. Bias in the interview situation can lead to the securing of incorrect information. One everpresent source of bias is due to the individual differences from interviewer to interviewer. This source can never be completely overcome but can be minimized by standardizing the interview so the interviewer has a limited free choice in the procedure (1). Generally, there are two types of interviews: standardized and unstandardized or, often called, structured or unstructured. The structured interview has fixed wording and sequencing of questions. Unstructured interviews are more flexible and are primarily used for exploratory devices. As measurement devices, the unstructured interview is inadequate (1).

Babbie (2) and Wakefield (3) identified other sources of bias and are summarized below:

From the interviewer:

- 1) Inappropriate appearance or behavior. Untidy appearance and over dressing will interfere in establishing a good rapport between interviewer and respondent. Generally the interviewer should dress in fashion similar to that of the people being interviewed.
- 2) Taking liberties with questions. This may elicit different types of responses and affect the data.
- 3) Variation in the interviewers' probing technique. Impromptu explanation of questions should be avoided, however, open-ended

probing questions may need to be used when the respondents misinterpret questions, contradict themselves or simply when more information is needed on an item. Avoid the "Do you really mean that?" tone of voice and be careful not to use suggestive probes.

- 4) Attitudes of the interviewer may affect the respondent. (Facial expressions or mannerisms may convey the interviewer's dislike of the situation or the individual.)
- 5) Record responses exactly. (Interviewer expectations may cause a response to be interpreted and recorded improperly.)

From the respondent:

- 1) Bias in memory of the respondent. (Food models and standard measuring devices can assist the respondent in recalling foods eaten and portion sizes.)
- 2) Intentional concealment of information. (Particularly a problem when very personal information is sought but also may be a problem when the respondent suspects the information may be used against him.)
- 3) Respondent who perceives the interview as unimportant and participates half-heartedly.

GUIDELINES FOR DIETARY RECALL INTERVIEWS

General Instruction for Interviews (4)

- 1) Record the foods and drinks on the 24-Hour Dietary Recall Form II as the child mentions them. Obtain specific descriptions concerning the food or drink. Do not worry about amounts until all foods are recorded. Record where meal was eaten, using appropriate code.
- 2) Use the Probing Questions to get complete and specific information about types of foods eaten; e.g., if the student says he/she had a sandwich find out what kind of sandwich, if it had butter or mayonnaise or salad spread in addition to the filling, or what kind of bread, and approximately how many slices of tomatoes.
- 3) Call attention to the posters with food models to assist students in identifying types of foods eaten.
- 4) Then proceed to get information on quantities consumed. Use measuring cups, spoons, and graded sizes of glasses from interview equipment kit to assist students in identifying quantities. Enter in the amount column on form.

- 5) Also, use posters with food models to assist in determining portions; e.g., if child has eaten the same size serving as the model then record as  $1 \times \text{mdl}$ ; if child says he has eaten less or more than the model, record as a fraction or multiple of the model ( $\frac{1}{2} \times \text{mdl}$ ).

#### Some Do's and Don'ts for Interviewers (4)

- 1) Do be friendly, but gently firm, when you ask your questions.
- 2) Do try to obtain the desired information as quickly as possible, but do not hurry the child at any time.
- 3) Do express confidence at all times in the information being supplied by the child. Do not show surprise verbally or by facial expressions concerning anything said or done by the child.
- 4) Do avoid expressing approval or disapproval of any food/beverage reported by the child.
- 5) Do ask general questions to help the child remember what he/she has eaten but do not ask questions that suggest specific foods eaten.

#### Establishing Rapport with Respondents

Since the respondents are asked to volunteer a portion of their time and to divulge personal information about themselves, they deserve the most enjoyable experience that the researcher and the interviewer can provide (2). Establishing good rapport in an interview situation puts the respondent at ease, yet maintains the authority of the interviewer. This can often be accomplished by initially talking about non-food items until the child becomes comfortable with the interviewer. A few minutes is usually long enough to establish this relationship.

#### Sequence of Interview

- 1) Follow narrative and instructions on form called Introductory Narrative for 24-Hour Dietary Recall.
- 2) If the interview takes place in the morning, first ask the child about foods eaten that morning, then the foods eaten on the previous day. Progress backward timewise to approximately the same time of day the interview is being conducted. This should usually include a morning, noon and evening meal plus snacks. Enter meal code in appropriate column if student identifies meal (4).
- 3) If the interview takes place in the afternoon, ask first about foods eaten within the past few hours, then during the morning and at home before coming to school. Proceed to the previous

day, progressing backward. Include those foods and drinks consumed within the last 24 hours (4).

#### Completion of Recall Data (4)

As soon as possible after the on-site visit, review forms and complete or clarify as needed. If "model," or a portion thereof, were entered as quantity, refer to List of Food Models and enter exact quantity. Using code sheet, enter Meal Code and Where Code for each food in appropriate columns on recall form. Also, determine food code and quantity code from listing of foods in data base and enter appropriate codes.

## PROBING QUESTIONS

1. Was the milk: whole, two percent, skim or chocolate?
2. Did you have sugar on your cereal? Was your cereal cooked, dry or presweetened?
3. Was your toast white, whole wheat, rye, raisin, or other? What did you put on it?
4. Were your mashed potatoes real or instant? Did you put anything on them?
5. Did you have lettuce, tomato, mayonnaise, ketchup, mustard, butter, pickles, cheese, or onions on your sandwich?
6. Did you have two slices of bread for your sandwich?
7. Did you have dressing on your salad?
8. How were the vegetables cooked? Did you have butter or sauce on your vegetables?
9. Did you put sugar or anything else in your tea or coffee?
10. What kind of juice did you have at breakfast? Did it come from a can or bottle, or powder? Was it pure juice, i.e., Minute Maid, Scotch Treat, Dewey Fresh, etc.? Was it artificial, i.e., Awake, Tang, Bright Day, etc.?
11. What kind of cookies did you eat? Were they homemade or store-bought? Do you know the brand name? Did they have chocolate chips, peanut butter, oatmeal, or anything else in them?
12. What kind of pie or cake did you have? Did it have any topping, frosting or fruit on it?
13. Did you have any fruit in your cake or jello? Was it canned, frozen or fresh?
14. Did the pop you drank come in a can or a regular or a giant size bottle? Was it diet?
15. Were your crackers saltines, whole wheat, graham or other?
16. Were your eggs fried, scrambled or poached?

I.D. Number: \_\_\_\_\_ Date of recall: \_\_\_\_\_

Day of week of recall: \_\_\_\_\_ Recall taken by: \_\_\_\_\_

Time of interview: \_\_\_\_\_

1. Do you take vitamin and/or mineral supplements?

\_\_\_\_ yes

\_\_\_\_ no

(If answer is yes)  
how many per day? \_\_\_\_\_

per week? \_\_\_\_\_

2. What kind? (Insert brand name if known)

Multivitamins \_\_\_\_\_

Ascorbic acid \_\_\_\_\_

Vitamins A and D \_\_\_\_\_

Iron \_\_\_\_\_

Other \_\_\_\_\_

3. Are you on a special diet now?

\_\_\_\_ yes

\_\_\_\_ no

If yes, why are you on a diet?

\_\_\_\_ For weight reduction

\_\_\_\_ For weight reduction (doctor's prescription)

\_\_\_\_ For weight gain

\_\_\_\_ For allergy, specify \_\_\_\_\_

\_\_\_\_ For other reasons, specify \_\_\_\_\_

If no, have you been on a special diet within the past year?

\_\_\_\_ yes

\_\_\_\_ no

If yes, for what reason? \_\_\_\_\_

Directions: For the following list of foods, please indicate the number of times on the average you eat them per day, week, or month whichever is appropriate. Record the number of times eaten in the first column and circle the appropriate frequency in the last column. For example, if you eat bread 3 times per day, record this as:

|              |           |               |
|--------------|-----------|---------------|
| No. of times | Frequency | D = per day   |
| 3            | (D) W M   | W = per week  |
|              |           | M = per month |
|              |           | Y = yearly    |

If you never eat a food, put a 0 in no. of times.

|  | No. of times | Frequency |
|--|--------------|-----------|
| 1. Doughnuts                                 |              |           |
| 2. Sweet rolls                               |              | D W M Y   |
| 3. Pie                                       |              | D W M Y   |
| 4. Cake                                      |              | D W M Y   |
| 5. Cookies                                   |              | D W M Y   |
| 6. Baked desserts (other than pie, cake)     |              | D W M Y   |
| 7. Potato or corn chips                      |              | D W M Y   |
| 8. Snack crackers                            |              | D W M Y   |
| 9. Kool-Aid                                  |              | D W M Y   |
| 10. Regular pop (Coke, 7-Up, etc.)           |              | D W M Y   |
| 11. Beer, wine, or other alcoholic beverages |              | D W M Y   |
| 12. Candy or candy bars                      |              | D W M Y   |
| 13. Sugar used in drinks or on cereal        |              | D W M Y   |

APPENDIX E

Individual Physical Measurements of Adolescent Girls

Table 14. Individual physical measurements of adolescent girls

| ID number | arm circumference | triceps skinfold | arm fat area |

\*Percentages of 1980 Recommended Dietary Allowances for girls 15 to 18 years old (19).

The mean adequacy ratio (MDR) was calculated by averaging the percentage RDA values for energy and 11 nutrients, including supplements, with values over 100% being truncated.

Table 17. Individual dietary intakes, percentages of the 1960 RDA\* and MDR (without supplements) of adolescent girls

\*Percentages of 1980 Recommended Dietary Allowances for girls 15 to 18 years old (19).

†The mean adequacy ratio (MAR) was calculated by averaging the percentage RDA values for energy and 11 nutrients, excluding supplements, with values over 100% being truncated.

THE SELF-CONCEPT AS A FACTOR IN THE QUALITY OF  
DIETS OF ADOLESCENT GIRLS

## ABSTRACT

Adolescence is characterized by intense mental and physical growth. Many believe it is the time when the self-concept is developed and solidified. Physical appearance reportedly has a great effect on the self-concept of the adolescent female. The desire to be thin may lead to poor eating habits, such as skipping meals and following fad diets. Thus, the quality of their diets may be affected by their self-perception. Because of the paucity of information on the relationship between self-concept and dietary quality, this study was designed to investigate the effect of self-concept on the quality of diets of adolescent girls.

Scores for self-concept, measured by the Tennessee Self-Concept Scale (TSCS), and fat area values, calculated from anthropometric measurements, were obtained on 160 15 year old girls enrolled in physical education classes. A questionnaire was used to determine the frequency of consumption of low nutrient density foods, and 24-hour dietary recall interviews were conducted with a random subsample of 40 girls. Dietary data were analyzed for energy and 11 nutrients and expressed as percentages of the Recommended Dietary Allowances (RDA). Mean adequacy ratios (MARs) were calculated to assess dietary quality. Relationships among all variables were determined.

At the 5th, 50th, and 95th percentile, Kansas girls had larger arm circumferences, triceps skinfolds, and arm fat areas than their national counterparts. Their self-concept scores on most of the 11 categories of the TSCS were below the 50th percentile norms. Intakes of energy, protein, ascorbic acid, thiamin, riboflavin, niacin, and phosphorus met or exceeded the RDAs for these nutrients. Calcium, iron, magnesium, and vitamin B<sub>6</sub> intakes were less than their respective RDAs. Less than half of the girls

received MAR values greater than 75 percent and more than a third had MARs that were less than 66 percent.

MAR values were correlated negatively with carbonated beverages, candy, and baked desserts. Negative correlations also were found between fat area values and Physical Self scores. Self-Satisfaction scores were correlated positively with MAR values as were Family Self scores and carbonated beverages. Partial regression analysis showed that Self-Satisfaction and baked desserts affected MAR values significantly.
