## Abstract

Termites (Isoptera) are separated into morphologically and behaviorally specialized castes of sterile workers and soldiers, and the reproductive alates. Previous research on eusocial insects has indicated that caste differentiation has a genetic basis. Although much has been studied about the genetic basis of caste differentiation and behavior in the honey bee, *Apis mellifera*, termites remain comparatively understudied. Therefore, my objective was to compare the gene expression patterns of different castes of the termite *Reticulitermes flavipes* based on EST analyses and a microarray.

Soldier, worker, and alate caste and two larval life stage cDNA libraries were constructed, and ~15,000 randomly chosen clones were sequenced to compile an EST database. Putative gene functions were assigned based on a BLASTX Swissprot search. Categorical expression patterns for each library were compared using the *in silico* methods of BLAST2GO and r-statistics. I chose 2,240 unique-ESTs based on their putative function and sequence quality, which I used to fabricate a Combinatrix microarray. I used the microarray to compare expression levels between workers and soldiers from Kansas and Florida populations.

Seventy to ninety percent of the sequences from the ESTs of each caste and life stages had no significant similarity to those in existing databases. All libraries contained sequences with putative reproductive functions, which was unexpected in the non-reproductive soldier and worker castes. Sequences of interest that showed a putative bias among castes include a viral protein in soldiers and a possible chemosensory protein in alates, which may be involved in termite reproductive functionality or communication. The microarray showed increased

expression in the soldier caste of a sequence that matched tropomyosin and an increased expression level of a sequence that matched a PDZ-domain containing protein in some worker samples.

This study leads to several candidate genes of potential caste specific function, which can be further tested using functional analysis and between the different castes and life stages of *R. flavipes*. These genes include the sequences similar to *pebIII* and *RGS-GAIP*. I have also expanded upon the available sequences for this termite and utilized the r-statistic *in silico* method for the first time to putatively compare gene expression in the different castes of a eusocial insect. The *in silico* analysis allowed us to identify several genes which may show biased expression patterns in the different cDNA libraries and which may reveal caste-specific expression controlling important functions after further analysis. These candidates include: an alate-biased gene, which had a predicted function of neurotransmitter secretion and cholesterol absorption as well as a late larval-biased gene which was predicted to be involved in protein biosynthesis and ligase activity.

# CHAPTER 1 - Analysis of Caste-Specific Gene Expression Patterns

## INTRODUCTION

Examining the genetic basis underlying social development and behavior has been termed sociogenomics (1). Sociogenomics is predicated on two observations: “social life has a biological basis and thereby is influenced by genes and evolution” and “molecular functions of many genes are conserved across species” (1). Therefore, it is possible to examine social organisms such as termites, honey bees, ants, and social wasps in an ecological and molecular context to better understand the genetic basis, function, and origins of social behavior.

Termites (Isoptera) are a large group of diverse eusocial insects. Although eusociality is believed to have evolved only once in Isoptera, the ~2600 species show enormous diversity in life history, behavior, colony composition, morphology, physiology, ecology, and biogeography (2,3). *Reticulitermes* (Rhinotermitidae) species are found throughout much of the contiguous United States, with introduced populations in Europe, South America, and the Bahamas (4). *Reticulitermes flavipes* (Kollar) is the most common species in the United States. *R. flavipes* colonies, like other eusocial insects, consist of morphologically and behaviorally specialized castes. All individuals emerge from eggs as larvae, beyond which the development is somewhat flexible in that larvae may develop into nymphs and subsequently into dispersing alates, or into the sterile workers or soldiers (2). Workers maintain the termite nest, build tunnels, and take care of the brood, whereas soldiers are thought to defend the colony and possibly communicate general colony fitness. Workers and nymphs of this species may eventually develop into supplementary reproductives under the appropriate conditions (2,3).

Historically subterranean termites have been difficult to study, mainly due to the complicating factor of their cryptic living conditions and amorphous nest structure (2,5). However, the advent of genomic and bioinformatic methods has provided new opportunities to study these organisms. A macroarray study of *R. flavipes* (6) demonstrated the differences in gene expression differences among the different castes. Genes that exhibited differential expression between workers and soldiers included salivary cellulases, endoglucanases, tubulins, and troponins (6).

Some general trends found in other sociogenomic studies of additional species of termites include higher expression of the mitochondrial cytochrome oxidase-III subunit in workers and nymphs of *R. santonesis* (7); increased cytochrome P450 levels after methoprene application in soldier and presoldier fat body in *Hodotermopsis sjostedti* and *Nasutitermes takasagoensis* (8,9); and a gene found to be specifically expressed in *H. japonica* soldier mandibles termed SOL1 thought to be involved in soldier specific behavior (10).

In the well-studied eusocial honey bee, *A. mellifera*, there is a trend for behaviorally associated genes showing a C+G bias within promoter regions when compared to *Drosophila melanogaster* and also show more *cis* regulatory elements (11) as well as high levels of expression of ribosomal and hexameric storage proteins in queen and worker cDNA libraries (12). An EST analysis found that workers showed a bias for putative cell differentiation and hydrolase activity, while queens exhibited an upregulation of genes involved in metabolism and oxidoreductase activity (13).

Given that there has been no large-scale effort to identify expressed genes in termites my first objective was to characterize *R. flavipes* genes by analyzing an EST database of ~15,000 clones from three cDNA libraries constructed from workers, soldiers, and alates as well as two

cDNA libraries constructed from early and late termite larval stages. My second objective was to use a microarray based on a subset of the EST library to quantify gene expression differences between soldiers and workers, and validate these differences using quantitative real-time polymerase chain reaction (q-PCR).

## MATERIALS AND METHODS

### *Termites*

For the construction of the cDNA libraries *R. flavipes* workers, soldiers, alates, and larval stages were collected from a single colony on the campus of the University of Florida, Gainesville. The larvae were divided into early (putatively stages 1-2) and late (putatively stages 3-4) stages based on size. Several hundred individuals of each caste/stage totaling about 2 gm of wet weight were obtained and stored at -80°C until used. Termites from the same colony as those used for cDNA library construction were also used for the microarray analysis; in addition, I also collected *R. flavipes* workers and soldiers from a colony near Pillsbury Crossing (near Manhattan, Kansas).

### *cDNA Libraries*

mRNA isolation, cDNA synthesis and library construction was undertaken by AGCT Corp. (Cranston, RI). The cDNA was cloned into pBluescript II SK+ vector after digestion with *EcoRV* and *NotI*. Libraries were plated on LB medium with 50mg/litre ampicillin and grown at 37°C overnight. Several hundred colonies were randomly sampled from the plates for further processing and sequencing. Colonies were placed in 150µl liquid LB+ampicillin medium, grown overnight at 37°C, and stored at -80°C after adding 20µl of sterile glycerol. The colonies were then shipped on dry ice to the University of California-Riverside sequencing facility for sequencing using the T3 primer for 5'-ends of the clones.

### ***Sequence Analyses***

Using Sequencher (v4.7, Gene Codes Corp, Ann Arbor, MI), I removed the vector sequence and trimmed ends using program defaults. Sequences shorter than 150 bp were discarded from further analysis after trimming. ESTs were organized into contiguous sequences using the default parameters in EGassembler (<http://egassembler.hgc.jp/>), highly repetitive sequences were masked using the *Drosophila* RepBase library in EGassembler.

New gene discovery rate for each library was estimated by dividing the number of contiguous sequences by the total number of singleton sequences. Minimum average sequence insert sizes of cDNA clones were estimated by dividing the total number of basepairs sequenced by the number of ESTs in each library the maximum length is limited by the length of sequence. Thus, the actual length of insert is likely underestimated. Both singletons and contigs were assigned putative functions using a batch BLASTX reference search from the non-redundant protein database using BlastStation (v2.61, TMSoftware, Arcadia, CA), with an e-value  $\leq 1e^{-10}$ . Genes assigned putative housekeeping roles were identified using a list derived from Eisenberg et al. (15). Gene ontology (GO) comparisons were performed using BLAST2GO annotations (16). All EST sequences were submitted to the EST database, dbEST, at <http://ncbi.nlm.nih.gov/dbEST/>.

### ***In silico transcript abundance***

Relative transcript abundance in the ESTs derived from each caste-specific cDNA library was analyzed using r-statistics (17). The analysis is based on the entropy of partitioning genes among multiple cDNA libraries into contiguous sequences, and includes a quantitative measure of the degree of confidence in the results termed the r-value (17). I analyzed 20 sequences with the highest r-value composed of 10 contigs that returned a BLASTX hit with an e-value  $\leq 1e^{-10}$

and 10 that had no BLAST hit or a hit with an e-value  $\geq 1e^{-10}$ . I identified contiguous sequences by investigating the frequency of R among the contigs and chose the cutoff for genes of higher interest looking at where the slope of the line was not close to 1, similarly to the method used in Stekel et al., 2000 (Fig 1.6). Putative protein functional analysis of the latter group was performed using the protein function predictor (<http://dragon.bio.purdue.edu/pfp>), which pools sequences with similar structural motifs and assigns GO terms, to obtain an initial indication of gene function. I further validated the r-value measure of significant difference using a chi-squared analysis.

### ***Microarray Construction and Gene Selection***

For the microarray fabrication, I chose genes whose putative function was either coding for various enzymes or transcription factors. Of the 2,240 genes chosen for the microarray, 11 genes (cytochrome c oxidase subunit 1; actin-5C; cytochrome b; cytochrome c oxidase subunit 2; nucleotide-binding protein 2; 40S ribosomal protein S23; 60S ribosomal protein L10; NADH dehydrogenase 1 alpha subcomplex subunit 4; 40S ribosomal protein S14; cuticle protein 16.5, isoform B; histone H3.2) were utilized as potential positive controls, and evaluated after hybridization for constant expression patterns between arrays. Of the remaining genes 697 had an e-value  $\leq 1.0e^{-10}$ , 87 had e-values falling between  $1.0e^{-5}$  and  $1.0e^{-9}$ , 846 had an e-value  $< 1.0e^{-5}$ , and 599 returned no BLAST hits and were chosen as they were expected to be termite specific sequences, because they were not found in other organisms, with potential to influence caste-specific traits. Oligonucleotide probes (35-mers; one oligonucleotide per gene) and CustomArray 4x2K microarrays were designed and constructed for the 2,240 genes of interest by CombiMatrix, Corp (Mukilteo, WA).

### ***Total RNA isolation, Labeled-cDNA synthesis, and Microarray Hybridization***

I isolated total RNA from 10 whole body preparations of workers and soldiers using a modified TRIZOL reagent protocol, adding an RNA precipitation solution (0.8M disodium citrate and 1.2M sodium chloride) for better extraction efficiency during the precipitation phase of the protocol. cDNA synthesis, amplification, purification, and labeling was performed using the Amino Allyl MessageAmp™ II aRNA Amplification Kit (Ambion, Inc. Austin, TX) and coupled to Cy3 dye for both castes tested. Labeled aRNA was hybridized to each array by first fragmenting the RNA using an RNA fragmentation solution (1M Tris Acetate pH 8.1 (2ml), KOAc (0.49g), MgOAc (0.32g), and water to 10ml). I took 1.2 µl of the fragmentation solution and added 2µg of labeled RNA, and added water to a total volume of 6µl. I incubated the solution at 95°C for 20 minutes and placed it on ice. Slides were prepared for hybridization using pre-hybridization solution (2X Hybridization Solution (75µl), Nuclease Free Water (51µl), 50X Denhardt's solution (15µl), denatured salmon sperm (1.5µl), and 1% SDS (7.5µl)), and placed into a hybridization oven at 65°C for 10 minutes on gentle rotation. I then added 30µl of hybridization solution (2X Hybridization Solution (15µl); DI formamide (7.5µl); fragmented RNA (6µl); denatured salmon sperm (0.3µl); 1% SDS (1.2µl); nuclease free water to 30µl) to each array. The array was incubated at 45°C in a hybridization oven on gentle rotation overnight. Arrays were washed using progressively lower concentrations (6X, 3X, 0.5X) of SSPET solution (20X SSPE, 10% Tween-20, and Nuclease-free water) and finished by washing with a PBST solution (10X PBS (2ml); 10% Tween-20 (100µl); Nuclease-free Water (7.9ml)) until slides were imaged. I included 4 biological replicates each of the worker and soldier caste for a total of 8 hybridizations.

### ***Microarray Imaging***

Imaging was performed using an Axon GenePix 4000B Scanner at 500 PMT at the Kansas State University Integrated Genomics Facility; the image was acquired using GenePix (v6.1, Molecular Devices, Union City, CA). Digitized values for each spot were normalized and analyzed using GeneSpring (v10.0, Agilent Technologies, Santa Clara, CA). Slides were first normalized to the 50<sup>th</sup> percentile and then normalized to three internal positive controls (Contig456, MMS083\_C01, and MMS159\_D11). Analysis was performed on 3 biological replicates of workers and 4 biological replicates of soldiers, one of the microarrays had a high amount of background noise when visualized and was unusable for my calculations and discarded. Comparisons of fluorescence between worker and soldier microarrays were performed using a Student's t-test and p-values obtained for the various resultant fold-changes.

### ***Quantitative PCR for Validation of Microarray Results***

Results were verified using qPCR on 10 genes that had the highest up- or down regulation with  $\geq 2$ -fold change. Primers were successfully designed for 9 of the 10 genes (Table 1.1) using Beacon Designer (v7.5, Premier Biosoft International, Palo Alto, CA). Individual primer efficiency was quantified using a total of three dilutions (0.2X, 0.04X, 0.008X) of worker cDNA for each primer using three technical replicates; primer efficiency was determined using the iCycler software (v3.1.7050, Biorad Inc., Hercules, CA). Worker and soldier template expression levels were standardized using the housekeeping gene  $\beta$ -actin, which was previously shown to be the least variable reference gene for *R. flavipes* (30). The PCR program used in the analysis included 95°C for 5 minutes, 40 cycles of 95°C for 15 seconds, 55°C for 30 seconds, and 70°C for 30 seconds, after which time the data were collected. Efficiency was calculated and used in the qPCR analysis of worker/soldier expression ratios as described (21). qPCR for each

gene included 3 technical replicates using both worker and soldier total RNA from microarray experiments.

## RESULTS

### *General Library Analysis*

I sequenced 4031 worker, 3836 alate, 3548 soldier, 2111 early larval stage, and 1733 late larval stage cDNA clones from each library for a total of 15,259 clones. Each cDNA library had a minimum average insert size ranging from 570 to 1086 bp, gene discovery rate ranged from 47% to 60% and is generally expected to decrease with increased sequencing (Table 1.2). Each EST library had a high proportion of sequences with no known BLASTX hit, of the remaining sequences the worker and late larval libraries had the highest proportion of ribosomal sequences and both larval libraries exhibited the highest level of sequence redundancy after the BLASTX analysis (Table 1.2). Each library contained between 5% and 16% of sequences that had a significant e-value and were used in the GO analysis.

### *Sequence Analysis*

Analysis of the sequences using level two cellular component GO putative terms showed similar proportions across castes with cell part, cell, and organelle being the most frequent term assigned to sequences (Fig 1.1A-E). The GO analysis of level two molecular function terms showed, in general, that the binding term was the largest proportion in each library followed by catalytic activity, except for the late larval library where the pattern was reversed (Fig 1.2A-E). The final GO category I investigated was that of biological process. The proportion of level two terms showed an abundance of those associated with cellular and metabolic processes (Fig 1.3A-E). Interestingly, I also discovered a portion of sequences that were putatively associated with reproductive functionality, even in sterile castes. The alates showed the highest number and

variety of sequences assigned with a reproductive term, but soldiers also exhibited a large number of genes putatively associated with reproductive functions (Fig 1.4).

Due to the small number of BLASTX hits, I was unable to obtain many GO terms in proportion to the number of total EST sequences to use in the GO analysis. Therefore, I chose a less stringent significance threshold than normally utilized with p-values  $\leq 0.15$ ; no differences were found with a smaller p-value threshold for significant GO abundance between libraries.

### ***In Silico Analysis- Significant BLAST Hits***

As previously mentioned, the r-statistic analyses were split into two separate groups of sequences, those that returned a significant BLASTX hit, and those that did not. For the first group, (Table 1.3) the soldier library showed a bias of sequences that putatively matched a protein from the cricket paralysis virus. Two separate contigs with an abundance of soldier and alate transcripts showed different sequence identity to the same ejaculatory bulb-specific protein in *Drosophila melanogaster* [Flybase:CG11390]. Three other contigs showed a bias within the alate library that matched closely with cytochrome c oxidase (*Blatella germanica*), cellulase b (*Cellulomonas fimi*), and ATP synthase subunit a (*Drosophila simulans*). A number of contigs also showed overrepresentation from the early and late larval stage libraries and included cytochrome b (*Drosophila sechellia*), tropomyosin (*Dermatophagoides farinae*), troponin c (*Tachypyleus tridentatus*), cytochrome oxidase subunit 3 (*Drosophila melanogaster*), and 60s ribosomal protein l31 (*Spodoptera frugiperda*).

### ***In Silico Analysis- Protein Prediction***

The second in silico analysis of the EST libraries (Table 1.4) was analyzed using the protein function predictor. Proteins associated with anti-bacterial humoral response and

translational elongation were two protein functions predicted from contigs with a transcript bias in the soldier cDNA library (Table 1.4). Putative functions of neurotransmitter secretion, cholesterol absorption, cell adhesion, and hydrolase activity were predicted for contigs with a transcript bias in the alate cDNA library. Predicted protein functions of protein synthesis, ligase activity, regulation of transcription, metabolism, stress response, cell adhesion, and spermatogenesis were discovered in contigs with a transcript bias of the late larval stage cDNA library.

### ***Microarrays Combined***

I analyzed the microarray results together and separately based on location of sampling of termites to detect potential differences in gene expression between Kansas and Florida samples, while evaluating gene expression patterns conserved across populations. I found one gene expressed at 42-fold greater (p-value <0.05) in the worker caste, this gene returned no BLASTX hit with an e-value<1.0E<sup>-10</sup>. Among the remainder, I found 141 genes that showed >2-fold higher in soldiers as compared to workers (Table 1.5) and 411 with >2-fold higher in workers versus soldiers (Table 1.6). Due to the small number of significant expression differences (p-value<0.05) between castes in my combined location analysis, I examined fold-change differences in the microarrays. I set aside the top and bottom 5 fold-change genes as possible genes of interest to validate using qPCR. The top fold-change sequences in worker expression had no known function and did not match any proteins in the BLASTX database (Table 1.6). Those genes that exhibited lower expression in workers relative to soldiers matched tropomyosin (99% amino acid identity), RGS-GAIP (68% amino acid identity), probable exocyst complex component 4 (57% amino acid identity), and troponin C isoform 1 (81% amino acid identity). The fifth sequence had no matches in the BLASTX query (Table 1.7).

### *Microarrays of Florida Samples*

My second analysis of the data was of only the Florida microarrays as I had insufficient replicates of successful arrays from Kansas for accurate analysis. I found 20 significant ( $P<0.05$ ) genes with expression differences (Table 1.8) 11 of which were overexpressed in workers and 9 that were overexpressed in soldiers. Expression differences between these two castes ranged between 1.0 and 1.4 fold.

### *Quantitative PCR for Validation of Microarray Results*

Expression patterns were variable across biological replicates for all genes of the combined microarray dataset except for troponin C, which was consistently overexpressed in soldiers across all samples (Table 1.9). Although the putative RGS-GAIP exhibited variable expression patterns in several biological replicates of the qPCR validation, its expression was greatly increased in two of the worker samples as compared to soldiers (12- and 4-fold expression difference).

## DISCUSSION

### *General Library Analysis*

The gene discovery rate of sequences for each library ranged from 47% to 60%, which is indicative of a good rate of unique genes found for each caste; however, it does indicate a need for more sequencing from each library. The high level of unknown genes in this analysis indicates a high probability of unique sequences from *R. flavipes* specifically which are not currently available is most likely due to the reduced number of related sequences in public databases.

About 12% of the sequences in the worker and late larval libraries were associated with ribosomal function; however a previous study on termites (20) found lower levels of rRNA gene expression in workers; an exception to this general trend was an 18-S-rRNA-like sequence. My results may be somewhat biased as I was not specifically testing expression levels and focused on transcript abundance of these sequences in workers.

In the GO analysis I found that a large proportion of genes in all the libraries were associated with reproductive function. This may reflect the possibility that the workers have the ability to express sequences that can be co-opted under certain conditions to allow them to reproduce, such as in the absence of a primary reproductive; however, it is also possible that these genes have other functions and are not restricted to reproductive function. Most of the other terms involved binding or translation/transcription control, which I took into account while choosing sequences for construction of the microarray. The fact that most of the GO term representation patterns were repeated among libraries is understandable as I hypothesize that each termite shares the same genetic code, but regulation of post-transcriptional expression most

likely causes much of caste-specific differences. More rigorous testing of this hypothesis is needed before I can draw any general conclusions from these patterns.

This general trend of expression may not be maintained across all populations of termites as it was shown between Kansas and Florida populations in this study. I also did not control for sample selection, choosing termites randomly without concern for sex, age, or environmental conditions, which also could have obscured some caste-specific expression patterns. In addition, the implications of expression differences based on ESTs alone are tentative and may not be reflective of an actual expression difference.

### ***In Silico Analysis***

The most bias from the first grouping of sequences used for the *in silico* analysis was composed mostly of soldier singletons which matched a viral protein; this raises the possibility of viral contamination in the soldier library, or soldiers could have a protein similar to the sequence of the viral protein that is expressed at a higher level than in the other castes.

Two contigs that showed transcript over-representation in soldier and alate libraries matched a protein that was similar to an ejaculatory bulb-specific protein in *D. melanogaster* *pebIII*. This protein was implicated in odorant binding due to its expression in glands that produce pheromones in male flies and its sequence similarity to a odorant binding protein in *Mamestra brassica* that has been implicated in sexual attraction and repulsion (22); however, recent research has also reported this protein from fly heads (23), the female reproductive tract (24), and in response to viral challenge (25). This sequence was also found to match a chemosensory protein in *A. mellifera* (AmelCSP3); however, the expression pattern of this protein after a Northern blot analysis seemed to indicate a function in cuticle maturation based on its timing of expression (26). The termite sequence showed a sequence identity to the *D.*

*melanogaster* sequence [REFSEQ:NP\_524966.1] of 55% (e-value: 2.00e<sup>-28</sup>) and the *A. mellifera* sequence showed a 52% identity to the *R. flavipes* sequence I recovered (e-value: 2.00e<sup>-26</sup>). It is unknown what role these proteins play in termites, but they are about 97% similar to each other, with a larger proportion of the transcripts being of alate origin, implicating that alates have a higher number of transcripts produced than the soldiers. One intriguing possibility is that the alates produce this as a method of reproductive suppression of other castes, or it is possibly involved in termite communication.

Three other genes showed a significant transcript bias in the alate library. The first gene was most similar to the mitochondrial cytochrome c oxidase subunit. Higher levels of cytochrome c oxidase expression were previously discovered in dealate ants and hypothesized to be involved with programmed cell death of wing cells (27). The second gene matched the cellulase b gene in the bacteria *Cellulomonas firmi*; the prevalence of this in alates may simply reflect higher levels of symbiont load in alates relative to other castes as the gene is of bacterial origin. One reason why this pattern may be seen is that alates need extra stores of symbionts to establish the bacteria in workers and soldiers in a nascent colony, to assist in cellulose degradation (3). The final gene matched an ATP synthase subunit a gene that could be an indicator of higher initial energetic needs of colony founders.

The remaining genes analyzed showed biases primarily in the early larval stage libraries. Most of the genes that matched are involved with general energy production and muscle contraction (28). These could indicate a higher need for energetic reserves and muscle contraction as larvae perform general colony tasks rather than specialized tasks such as those by older workers and soldiers.

My other grouping of r-statistic analysis was of genes that showed a library bias of singleton composition that did not have a significant BLAST hit, but which was submitted for a putative function prediction based on the protein translation.

My results suggested that soldiers have a high level of expression of genes putatively involved in immune function, whereas in other eusocial insects, the pattern of increased immune investment was seen in the reproductive caste (29). It is important to consider that this sequence was on the lower end of my r-value acceptance levels, and thereby its representation was not as biased for one caste or the other as those with higher r-values. These predicted functions may also indicate that soldiers invest more in antibacterial responses because termites in general are exposed to bacteria and other microbes in the soil and wood. This abundance may also indicate that the soldiers used in cDNA library construction may have been recently challenged by a microbial infection.

The two transcripts with an alate bias included proteins putatively involved in neurotransmitter secretion, cholesterol absorption, cell adhesion, and hydrolase activity. These may indicate a higher level of investment by the alates in brain and cell-cell communication that may be helpful in colony establishment and mate recognition. Many of the transcripts from late larval stage library have a putative function involved with energetic needs and metabolism. I also found a gene predicted to be involved with spermatogenesis in the late larval library, but as workers can eventually develop into reproductive individuals (2), it is possible that late larval stages express some proteins with putative reproductive functions in case there is an opportunity to become secondary reproductives (2). A general pattern in my analysis was the existence of genes putatively associated with reproduction that were discovered even within sterile caste libraries. This is unexpected but it is possible that these genes are regulated post-transcriptionally

or they exist in sterile castes because sterile castes can differentiate into supplementary reproductives under certain conditions (2). Further analysis of these larval individuals is needed to assess reproductive capabilities and eventual caste determination.

Previous studies have implicated two hexamerins (*Hex-I* and *Hex-II*) in soldier-worker differentiation in *R. flavipes* (19,30). I recovered both hexamerin I and II in worker, alate, and early larval stage libraries and hexamerin-I in the soldier library; however they did not exhibit differential expression in the *in silico* analyses, most likely because I was not examining the transitional form between soldiers and workers, as was done in the previous studies.

### ***Microarrays of Combined Samples***

The higher expression levels of tropomyosin seen in soldier populations is most likely due to the larger size of individuals of that caste when compared to workers and the presence of strong musculature associated with mandible function. The other pattern of interest seen in the analysis was the higher expression level of the RGS-GAIP sequence, which contains a single PDZ domain, in some of the worker comparisons, which is similar to kermit in *D. melanogaster* [REFSEQ:NM\_143771.2]. PDZ domains are well conserved across kingdoms being found in many diverse taxa. The PDZ domain-containing proteins are found in many neuronal junctions, have been implicated in proper function of tight junctions, and the construction and maintenance of molecular and neuronal signaling complexes (31-34). They have been found to accomplish this by bringing signaling components in closer proximity to one another allowing for more efficient signaling, and can act on polarized epithelial cells for proper orientation to avoid tumorous cell growth (31). The *D. melanogaster* *kermit*, was shown to affect planar polarity of pupal wing development (35). *Kermit* was originally isolated from *Xenopus laevis* and was found to be expressed throughout its development. It was found to interact most strongly with frizzled-

3, and when *kermit* functionality was blocked it inhibited neural crest induction, while over-expression of the specific frizzled sequence lead to an overwhelming translocation of marked *kermit* to the membrane, with very little in the cytoplasm (36). The suspected homologue of *kermit* in humans is GIPC1 [GenBank:AF089816] and has been found to be highly expressed in breast cancer cells (37). In addition, GIPC1 was also found to bind myosin VI (38) and possibly interact with another protein (APPL) through interactions with other GIPC1 monomers (39) forming a complex, which is proposed to shuttle clatherin-coated vesicles and be involved with TrkA signaling (40). These findings all seem to suggest a possible role for this protein in cellular growth and polarity in insects and a possible signalling role in humans. In termites its role could be similar, by some undiscovered trigger workers will develop into soldiers producing the characteristic of enlarged head capsules and body size. It is tempting to interpret the lower level of expression of this protein in some soldier samples as some mechanism for maintaining or creating the new body plan of soldiers during the worker-soldier transition. However, this cDNA sequence needs to be fully sequenced and qPCR experiments on samples of workers that I know are currently transitioning to the soldier caste are needed. The implications of fully characterizing this gene and understanding its functionality would help us to understand how termites can undergo such a radical change and to better realize the genetic underpinnings behind controlled cell division and expansion.

The remaining sequences from the qPCR validation did not show an expression difference of greater than 2-fold and were not consistent between samples. The variable expression patterns found in the qPCR of the combined locale array set can be explained by differing expression produced by exposure to different environmental conditions, as well as differences produced by my random sampling design pooling 10 individuals from the same

sample which were most likely composed of different sexes and ages, which was done in order to extract sufficient cDNA for the microarray hybridization.

### ***Microarray Analysis of Florida Samples***

Although I found several significant expression differences, the fold-change between workers and soldiers was low (Table 1.9). Further expression analysis of these 20 sequences is needed using qPCR methods to confirm the validity of these patterns seen in the worker and soldier comparisons. By separating my analysis by location I decreased the amount of biological replicates being compared and this may have introduced some bias in the analysis and indicates that additional Florida replicates are needed. I was unable to effectively analyze the Kansas microarrays due to the small number of successful array replicates, but an increased number of microarrays with specific focus on each location will yield better results.

## **CONCLUSION**

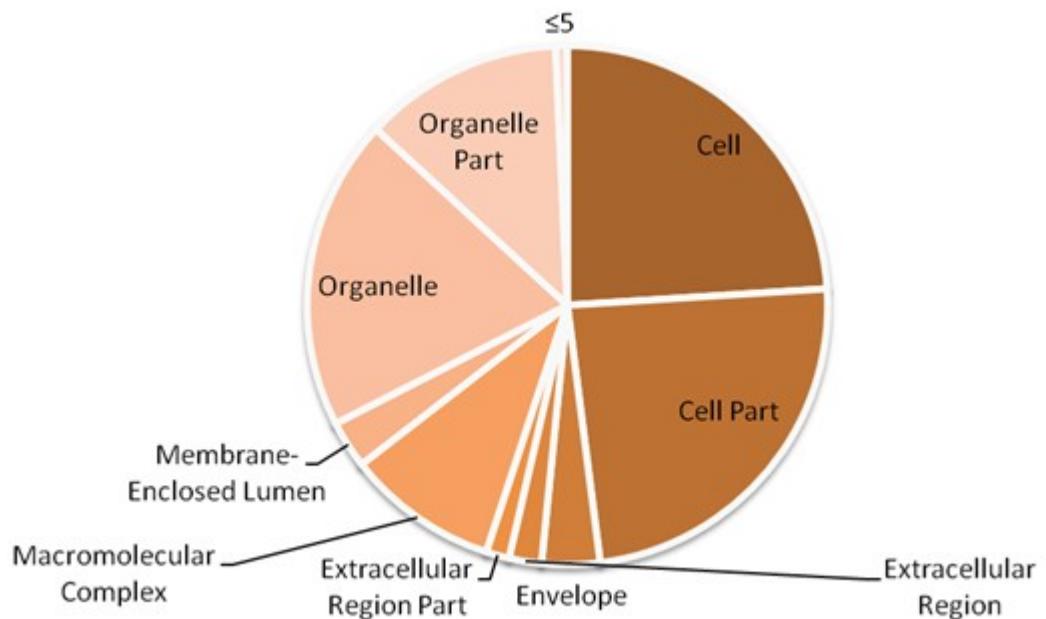

In conclusion, I presented the EST analysis of 15,351 randomly chosen cDNA fragments from 5 different cDNA libraries. As indicated, relative to the honey bees, little is known about the genetics of caste differentiation and behavior in the termites. Therefore, the EST database reported here is likely to be a valuable resource for future studies on the sociogenomics of termites in general and *R. flavipes* in particular. In addition, the in silico analysis revealed several patterns that could be the subject of future functional genomics studies. For example, the caste-biased transcript abundance of several genes indicates that these proteins may be playing specialized roles in each of the castes or developmental stages. The presence of proteins putatively involved in reproduction in sterile castes is intriguing. It is possible that these proteins

play multiple roles or they may be subject to post-transcriptional or post-translational modifications.
