#### ACKNOWLEDGEMENTS

I would like to thank my advisor, Dr. Fred Oehme for his advice and help in obtaining and writing this project. I would also like to thank Dr. William Moore and Dr. Horst Leipold for their help and willingness to serve on my committee.

Dr. Steve Barkyoumb, Patricia Bullock, Mike Savides and Rachel Sheeley deserve thanks for their help; especially during some of the odd hours at which this project took place.

Without the help of my parents, the University of California at Davis, Crocker National Bank or the town of Mill Valley, California this thesis would have borne another name. Thank-you all.

## Introduction

Fenbendazole (FBZ) is used worldwide as an anthelmintic in a great variety of animals. In the United States FBZ is presently licensed for use only in horses.

Recent reports on the efficacy of FBZ in swine have shown that it may be effective enough to successfully compete on the commercial market in the United States with presently licensed swine anthelmintics. However, before FBZ can be licensed for use, scientific studies must be undertaken on numerous aspects of the chemical, including its safety for the target animal.

Since little information is available about the safety of FBZ in swine, this study evaluated the potential physical and pathological effects of acute FBZ use in growing pigs.

## SAFETY EVALUATION OF FENBENDAZOLE IN SWINE: III

Thomas F. Booze, BS, MS; Frederick W. Oehme DVM, PhD

### SUMMARY

Thirty female pigs, average weight 32 kg, were given fenbendazole (FBZ) for 3 days to test the safety of the drug. Dosages of 0, 3, 9, 15 and 25 mg of active ingredient/kg body weight were mixed with the feed. Clinical chemistry, hematology, urinalysis, gross and microscopic pathology, and bone marrow cytology revealed no significant adverse effects due to this drug.

---

The authors wish to thank Dr. Steven Barkyoumb, Patricia Bullock, Michael Savides and Rachel Sheeley for their assistance.

Fenbendazole<sup>a</sup> (FBZ), methyl 5-(phenylthio)-2-benzimidazole carbamate, was derived from parbendazole, itself an effective anthelmintic.<sup>1</sup> The anthelmintic activity of parbendazole was thought to be enhanced by the addition of a phenoxy group; however, the addition of a phenylthiol group created a more effective anthelmintic than did the phenoxy addition. Fenbendazole is effective against nematodes and trematodes<sup>2</sup> and in Ascaris suum, FBZ is believed to exert its anthelmintic effect by interfering with the utilization of glucose and glycogen.<sup>3</sup> In Hymenolepis diminuta a neurotoxic effect has been observed.<sup>4</sup>

Fenbendazole has been used as an anthelmintic in a broad spectrum of animals, from laboratory animals to zoo animals, such as snakes and tigers.<sup>5,6</sup> The oral LD<sub>50</sub> in rats and mice was estimated to be greater than 10,000 mg/kg.<sup>7</sup> A dose of 5000 mg/kg was given to sheep without clinical effects.<sup>7</sup> The wide margin of safety of FBZ is important when it is difficult to estimate an animal's weight or when the correct dosage is not possible. Because FBZ is highly effective against Trichuris suis and Ascaris suum in the pig when given in doses of 3 or 5 mg/kg over a 3 day period,<sup>8</sup> its use in that species is of economic significance.

Recent reports on the safety of FBZ in swine have shown a dose-related leukopenia, involving lymphocytes and segmented neutrophils, when FBZ was given orally at doses of 25, 75 or 125 mg/kg for 5 days, or when it was given orally at 2000 mg/kg for 14 days. A dose-dependent increase in sorbitol dehydrogenase (SDH) was also noted.<sup>9,10</sup> This paper reports further evaluations of the safety of FBZ when given in 3 daily doses of 0, 3, 9, 15 or 25 mg/kg to growing pigs.

## MATERIALS AND METHODS

Animals, Housing, and Feeding - Thirty-one healthy, 25 kg female, Yorkshire pigs were obtained from a local supplier and randomly housed 3 to a pen in a barn with cement floors. The pens were thoroughly washed each morning before feeding. Feed consisted of a commercially made milo-supplement mix (16% protein). Water was freely available from automatic waterers.

The pigs were acclimated for 21 days. The experimental period consisted of a 10-day pre-dosing period (days -10 to -1), a 3-day FBZ dosing period (days 0 to +2), a 10-day post-dosing period (days +3 to +12), and necropsy on day +13. To monitor biochemical, hematological, and urinary parameters, blood and urine samples were collected on alternate days throughout all phases. Starting with a pre-dosing period to establish baseline values, collections took place on the following days: -10, -8, -6, -4, -2, 0 (dosing initiated), +2 (dosing ceased), +4, +6, +8, +10, +12, +13 (necropsy).

Due to limited housing facilities and the need to give each pig a separate pen during the dosing period, the pigs were randomly divided into 2 study groups (A and B) of 15 apiece. Each group was then further randomly divided into 5 sub-groups of 3 pigs each. Each pig in the sub-groups received one of the following daily doses for 3 days in individual pens: 0, 3, 9, 15 or 25 mg FBZ/kg body weight.

The calculated dose of FBZ was mixed with 1/4 of the daily feed ration and placed in a metal feed dish for consumption. Once this mixture of FBZ and feed was consumed the remaining ration of feed was given. The FBZ-feed consumption generally required less than 5 minutes.

The general health of the pigs was observed daily. Their body weight and body temperatures were determined weekly. Weighing of the pigs was accomplished one at a time, on a weighing platform. Body temperatures were taken with a digital thermistor thermometer<sup>b</sup> and rectal probe<sup>c</sup> while the pig was in the weighing stall.

Blood and Urine evaluation - All sampling was done early in the morning before feeding. Blood samples were obtained via cranial vena cava puncture and collected in ethylenediaminetetraacetic acid (EDTA), heparin, citrate and blank Vacutainer<sup>d</sup> tubes for clinical chemistry and hematology evaluations. Blood urea nitrogen (BUN), creatinine, alkaline phosphatase, total serum protein, calcium, sodium, potassium, carbon dioxide, glucose, albumin and inorganic phosphorus were determined by the SMA 12/60.<sup>e</sup> Sorbitol dehydrogenase was determined using Sigma<sup>f</sup> reagents and Biochromatic analyzer.<sup>g</sup> Cholinesterase levels were determined by the Michel method.<sup>11</sup> Chloride was determined by the chloridometer.<sup>h</sup> Total plasma protein and fibrinogen were determined by the Refractometer TS Meter.<sup>i</sup> Prothrombin time was measured using Dade<sup>j</sup> reagents and fibrometer<sup>k</sup> (A separate non-dosed pig was used as a control for the prothrombin time determination). Red and white blood cells were enumerated with a Coulter<sup>l</sup> counter. A hemocytometer was used to count platelets.<sup>12</sup> The hematocrit was determined by the microhematocrit technique.<sup>12</sup>

Urine samples were collected in Pediatric Urine Collector bags.<sup>m,13</sup> Color was observed grossly. Specific gravity was determined with a refractometer.<sup>i</sup> Glucose, pH, ketones, protein, occult blood and bilirubin determinations were determined by Bili-labstix.<sup>n</sup> The presence,

in urine, of RBC's, WBC's, casts, bacteria and debris was determined microscopically.<sup>12</sup>

Pathology - On day +13 all pigs were euthanatized by an injection of T-61 Euthanasia Solution.<sup>13</sup> No carcass waited longer than 1/2 hour to be necropsied. Representative samples of liver, heart, kidney, spleen, lung, brain, stomach, small intestine, and bladder were fixed in 10% buffered neutral formalin immediately after excision from the carcasses. After 144 hours they were embedded in paraffin, sliced into 6 $\mu$  slices, mounted on glass slides, and stained with hematoxylin-eosin for pathological examination. Any other tissues that had gross abnormalities were also examined. Bone marrow contents were smeared directly onto glass slides and allowed to air dry. These slides were stained with Wrights-Leishman stain and microscopically examined.

Statistics - Values for each treatment group were compared and tested for significant differences ( $P \leq 0.05$ ) using analysis of variance.<sup>14</sup>

## RESULTS

Clinical parameters - The animals generally remained healthy and content throughout the course of the study. The one exception was pig #18, which died of an intestinal torsion on day +11. Body temperature occasionally was slightly elevated for some pigs, but all returned to normal the following day. Weight gains within the different dose groups were not significantly different (Table 1).

Blood chemistry - Cholinesterase, SDH, BUN, creatinine, alkaline phosphatase, total protein, albumin, calcium, sodium, potassium, phosphorus, glucose, chloride, and carbon dioxide remained within normal ranges.

Hematology - Only non-significant differences were noted in the hematology values measured (packed cell volume, fibrinogen, hemoglobin, total white and red blood cell counts, differential, platelet evaluation and prothrombin time).

Urine - The pigs receiving 9 mg/kg had a significantly lower specific gravity on day +6 (Table 2), but it was still within normal limits. All other parameters were within normal ranges.

Pathology - The most prevalent lesion noted was pneumonia, with 11 of the 30 animals being affected. Bone marrow counts were within normal ranges (Table 3). Gross and histological lesions are summarized in Table 4. There were no drug-related pathologic changes.

#### DISCUSSION

In a previous report a dose-dependent leukopenia was found in swine given oral doses of 25 mg FBZ/kg weight for 5 days. The present report was unable to repeat these findings. This is probably due to the fact that FBZ was administered for 5 days in the previous study while the present study administered FBZ for the 3 days which the manufacturer recommends for use in field applications.

Urinalysis from the 9 mg/kg pigs on day +6 had a significant decrease in specific gravity when compared to the 0 mg/kg pigs for those days, although it was within normal limits.<sup>12</sup> Decreased specific gravity occurs due to liver disease, chronic or acute nephritis, toxic nephrosis or other progressive kidney disease.<sup>15</sup> Kidney lesions were found in only 1 pig from this group and consisted of a few cysts which, in pigs, is not an uncommon occurrence.<sup>15</sup> Specific gravity decrease is also a normal response to physical factors such as increased water intake. Neither

clinical chemistry or pathology supported any drug related cause and this decrease did not occur in any other group.

The most prevalent pathological lesion was pneumonia. It was generally distributed with only the 9 mg/kg pigs not being affected. This disease has been reported in as high as 50% of some swine herds.<sup>16</sup> During the course of this study, outside temperatures decreased to -5 C. These temperatures, along with the wet cement floors, from the early morning washings, could have contributed to the pneumonia incidence. Since the incidence was randomly distributed it is not drug-related.

Extramedullary hematopoiesis (EMH) was seen in 4 of the pigs. It appeared in 3 dose groups and was evenly distributed in the limited number of pigs affected. Anemia may cause EMH but clinical chemistry or hematology did not confirm this. Extramedullary hematopoiesis occurs in most animals around birth and in some species is present throughout life.<sup>15</sup>

**Fenbendazole in Swine**

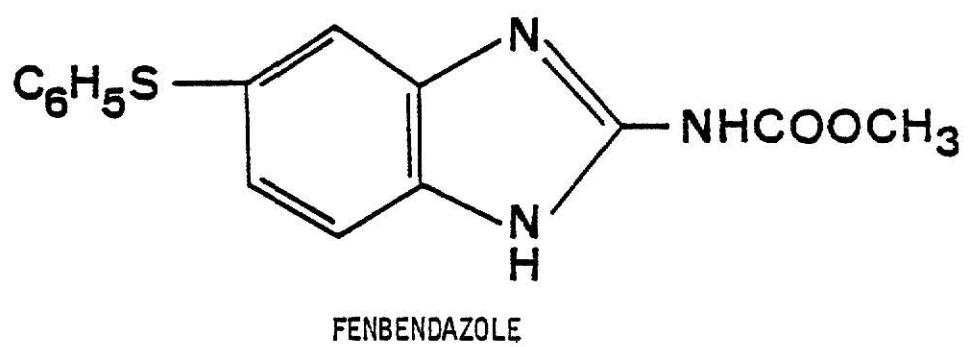

Figure 1. methyl 5-(phenylthio)-2-benzimidazole-carbamate

## INTRODUCTION

Fenbendazole FBZ, methyl-5-(phenylthio)-2-benzimidazole carbamate is an almost colorless powder with a molecular weight of 299.2 (Figure 1). It melts with decomposition at 233°C and is freely soluble only in dimethylsulfoxide (DMSO). Its ultra-violet (UV) spectrum in methanol shows maximum absorption at 298 nm.<sup>1</sup> Fenbendazole is presently available in 6 formulations all designed for oral consumption.

Fenbendazole is thought to work by interfering with the parasites' metabolism. In studies on Ascaris suum FBZ was found to inhibit glycogen formation and breakdown.<sup>2</sup> In Hymenolepis diminuta FBZ exerts a neurotoxic effect which causes the suckers to lose form and function. Eight hours after treatment the parasite becomes paralyzed and soon dies.<sup>3</sup>

Fenbendazole is used worldwide in a variety of animals from birds to elephants. In the United States, it is presently licensed for use in horses only.

## USE

Internal parasites of swine represent a large part of the one quarter of a billion dollar annual profit loss of swine producers.<sup>4</sup> This loss not only affects the producer it ultimately affects the consumer as well. Kidney worms (Stephanurus dentatus) cause an estimated \$73 million annual loss to the swine industry.<sup>5</sup> As many as 51% of swine livers in North Carolina were condemned as unfit for human consumption. Over 90% of these livers were infected with a combination of ascarid (A. suum) and kidney worm lesions.<sup>4</sup>

The most prominent member of the kidney worm family is Stephanurus

dentatus. Stephanurus dentatus lives in the southern and eastern parts of the United States and in warm climates such as Hawaii and Puerto Rico, but has been reported moving northward into Canada.<sup>6</sup> Stephanurus dentatus has the capability of migrating to other parts of the body, most notably the liver. They cause emaciation, poor weight gain, ascites, abscesses, fibrosis and adhesions. Studies on swine infected with these worms show that they require 183 kg (404 lbs) more feed per pig and an additional 59 days to reach market weight.<sup>6</sup> In studies done in North Carolina, FBZ was orally administered to sows in single doses of 10 or 15 mg/kg, and in doses of 2, 3 or 5 mg/kg daily for 3 days. On day 56 the sows were necropsied. While evidence of previous infections in the kidney, perirenal fat, adipose tissue and liver were found, no live mature or immature kidney worms were present.<sup>7</sup>

The most damaging parasite in swine is the roundworm, Ascaris suum. Ascaris suum is ubiquitous, appearing in as many as 100% of hogs examined in the United States. In 1962 it was estimated that A. suum caused a loss of \$200 million to the U.S. swine industry. One estimate put the annual egg production of A. suum at 700 tons with the annual worm production at 5000 tons.<sup>6</sup> The reason for this tremendous output is the female's ability to lay 23 eggs per second, or 2 million eggs per day. These eggs are extremely resistant to environmental conditions and may remain viable for up to 6 years. Morphologically, though not physiologically, this species is the same as that found in man, in whom 25% of the world's population is infected.<sup>8</sup>

Ascaris suum enters the pig when the 2nd stage larvae, which is still in the egg, is eaten. The eggs hatch in the intestine and the larvae migrate through the intestinal wall into the blood. They are then

carried to various organs of the body where they die or begin to mature. Two important organs are the liver and lungs. The larvae are carried to the liver where they mature. They may then migrate through the liver and be carried to the lungs where they can be coughed up and swallowed again. The larvae then lodge in the intestinal tract where they mature into egg laying adults. While eggs may hatch and larvae may migrate into most vertebrate hosts, they will only mature in an "appropriate" host which will supply the parasites living requirements.

There are two periods in which the ascarids exert an effect on swine: 1) When the larvae are migrating through the liver; and, 2) After the larvae have returned to the intestine to mature and lay eggs. During the migration period *A. suum* may cause white spots in the parenchyma of the liver. These may be of two different types depending on whether the larvae have stayed or have moved on through.

The two types of white spots are the granulation tissue-type and the lymphonodular type. The granulation tissue-type consists of a central lesion, intralobularly located, with a small (0.15 mm) granuloma containing larval remnants. The size of the spot depends on the length of time the larvae was in the area. A large spot is created when a larva gets stuck in a lobule exposing the surrounding area to its irritating action for a long period of time. Ascarid larvae are rarely found in the smaller spots. If the spot is fresh a mass of eosinophils may be seen surrounding the area. If an older spot there may be a caked mass of eosinophils with pyknotic nuclei.

The lymphonodular spots are large (1-5 mm) and firm consisting of lymphocytes and connective tissue forming a nodule around a larval remnant. In some of the older nodules the larvae found are dead and

morphologically altered; few eosinophils may be found. This may indicate that some of these older nodules are formed from older granulation-type tissue. Eventually (2 months) the white spots will regress. These white spots are causes of liver condemnations; an average of 2.1% of swine livers have been so condemned.

In lungs the migratory larvae may cause pneumonia (verminous), atelectasis, edema, hemorrhagic foci, and emphysema. Ascaris suum may also exacerbate other existing conditions, such as viral pneumonia.

Once the larvae have matured and started laying eggs in the intestine they will then compete with the host for available nutrition. Pigs infected with A. suum weighed 5 kg (11 lbs) after 3 months when compared to the control weight of 37 kg (82 lbs).<sup>6</sup> The adult may gnaw at the mucosa producing irritations and lesions. They may migrate into the bile duct, stomach, gall bladder and large intestine. The migration seems related to the amount of food in each of the areas. These migrations cause other problems, such as stenosis of the bile ducts which may bring about rupture and death from peritonitis. Nervous signs and stunted growth may also occur. Young pigs seem to be more affected than older pigs. If they have been exposed when young, older pigs develop a resistance against ascarids.<sup>6</sup> Fenbendazole was found to be 97-100% effective against A. suum when single oral doses of 7.5-25 mg FBZ/kg were employed. When given in doses of 3 or 5 mg/kg over a 3-day period it was found to be 99-100% effective.<sup>1,7,10,11</sup>

Nodular worms (Oesophagostomum spp.) cause an estimated \$26 million annual loss in the United States. They are found in as many as 47% of the swine of some herds.<sup>3,12</sup> Nodular worms generally reside in the large intestine and interfere with intestinal motility and food absorption.

They may produce intense inflammatory reactions which lead to the formation of nodules. Other effects include a mild toxemia, weakness, anemia, diarrhea, unthriftiness and even death. Unlike Ascaris spp. nodular worms affect older animals as much as or more than they affect young animals. Fenbendazole has been shown to virtually eliminate the adult stages of Oesophagostomum spp. when given at an oral dose of 5 mg/kg. Fenbendazole was less effective against immature stages of Oesophagostomum.<sup>13</sup>

Fenbendazole has also been shown to be effective against Haemonchus rubidus. At 3 mg/kg, 94% of these worms were expelled. Doubling of this dose resulted in the expulsion of 99% of the worms.<sup>1,13</sup> FBZ has been less effective against Strongyloides ransomi and Metastrongylus spp.<sup>14</sup> Trichuris suis is virtually eliminated when FBZ is given orally at 5 mg/kg for 3 days.<sup>7</sup>

In cattle FBZ has been used effectively against Ostertagia ostertagi, Haemonchus placei, Bunostomum phlebotum, Cooperia spp., and Oesophagostomum for both immature and adult stages at doses of 5-7 mg/kg (7.5 mg/kg is the recommended therapeutic dose).<sup>15,16</sup>

Studies in horses have shown that FBZ is effective against Trichonema spp. and large and small species of strongyles. It has also been shown effective against Parascaris equorum and Oxyuris equi.<sup>17,18,19,20,21</sup>

FBZ is effective against Toxocara canis, Ancylostomas caninum, Trichuris vulpis and Taenia hydatigena in the dog.<sup>22,23,24</sup> In the cat FBZ is effective against Toxocara cati, Ancylostoma tubaeforme and Taenia taeniaeformis.<sup>25</sup>

Domestic sheep studies show that FBZ is effective against Haemonchus contortus, Trichostrongylus colubriformis, Ostertagia circumcincta, Moniezia spp., Cooperia spp., Nematodadirus filicollis and Strongyloides papilliosis.<sup>26,27,28,29</sup>

In Bighorn sheep FBZ is effective against adult lungworm (Protostrognylus spp.). It is one of the few anthelmintics that this animal will readily eat without rejecting it due to taste.<sup>30</sup>

Fenbendazole is also effective against internal parasites in a wide variety of other animals both wild and domestic.<sup>14,30,31,32</sup>

#### KINETICS

Radiolabeled FBZ studies in rats, sheep, dogs, pigs and rabbits have shown that absorption of FBZ from the digestive tract is generally slow.<sup>33</sup> Animals with single stomachs absorbed the drug more rapidly than animals with multi-chambered stomachs.<sup>34,35</sup> Whether this is due to physical, biochemical or chemical differences is not known.

Approximately 1/3 of the FBZ is absorbed from the stomach in the pig.<sup>33</sup> Absorption of FBZ in pigs occurred rapidly (within 0.6 hours) after oral administration. In a study using 5 mg/kg of radiolabeled FBZ given orally to pigs, peak blood levels ( $0.86 \pm 0.18$  ug FBZ/ml) were reached 4 hours after dosing.<sup>36</sup> In another study using the same amount of chemically pure unlabeled FBZ, peak FBZ serum levels were lower ( $0.45 \pm 0.10$  ug FBZ/ml) and were reached later ( $10 \pm 2$  hours).<sup>36</sup> Peak blood levels ( $0.34 \pm 0.09$  ug FBZ/ml) in sheep weren't reached until 28 hours post-dosing (25% absorption).<sup>34</sup> Peak serum levels (0.58 ug FBZ/ml) weren't reached, in cattle, until 30 hours post-dosing.<sup>34</sup>

When swine were given a single oral dose of 5 mg FBZ/kg, the excretory organs contained the highest amounts of FBZ. When tested 2

days post-dosing, the liver had 0.66 ppm FBZ and the kidney had 0.62 ppm. The drug was found in muscle at 0.24 ppm and in the fat at 0.22 ppm. A week after dosing residues of FBZ in kidney, muscle and fat were below detection limits (< 0.1 ppm). Residues in liver required 2 weeks after dosing before falling below the 0.1 ppm detection limit.

The half-life ( $T_{1/2}$ ) of FBZ in serum following oral administration was 26 hours in sheep, 25 hours in cattle and 10 hours in swine.<sup>34</sup> The  $T_{1/2}$  in sheep was reduced by almost 1/2 when the dose of FBZ was injected.<sup>a</sup> When FBZ was injected into single stomach animals the  $T_{1/2}$  was unaffected, thus suggesting that the rate of absorption in sheep is dependent upon which of the various stomachs contains the drug.

Most of the orally administered FBZ is eliminated via the feces. In studies using radiolabeled FBZ, orally administered, 50-60% of the label was found in the feces of swine. Of this 43% was the parent compound, while the remainder consisted of 5 unidentified metabolites.<sup>b</sup> A later study identified one of the fecal metabolites as a sulfoxide derivative of FBZ.<sup>c</sup> The urine contained 30-35% of the radioactivity. Only 1% of the total administered FBZ compound was parent compound; the rest were 6 different metabolites, the chief one being 5-(*-*hydroxyphenylthio)-benzimidazole-2-carbamate.<sup>33</sup> Identification of all the metabolites in

urine and feces remains to be completed. The urine and fecal metabolites in swine appear to have the same characteristics as in other animals.<sup>33</sup>

The rapidity with which FBZ leaves the animal is important when considering its use in food animals because of concern with residues.

#### SYSTEMIC TOXICITY

The systemic toxicity of FBZ is low. No LD<sub>50</sub> has been able to be established for the pig or any other animal because of physical limitations. The pig has tolerated 5000 mg/kg without effect. In rats and mice the oral LD<sub>50</sub> is thought to be greater than 10,000 mg/kg.<sup>1,2</sup> Sheep have tolerated 5000 mg/kg without clinical reactions. Pigeons dosed with 400 mg/kg have shown no signs of toxicity.<sup>14</sup>

Acute toxicity studies in the pig have revealed only transient changes from normal baseline biochemical parameters. At doses of 500, 1600 and 5000 mg/kg respectively given for 1 day each, SGOT levels were slightly elevated the 3rd day after the last administration of FBZ.<sup>14</sup> Sorbitol dehydrogenase (SDH) activity was elevated for 7 days following the administration of 75 or 125 mg/kg, respectively, for 5 days. A dose-related leukopenia involving lymphocytes and neutrophils, occurred in pigs given 75 or 125 mg/kg, respectively, for 5 days. This increase developed on day +7 and continued to day +15. There were no significant lesions in any of the animals.<sup>37</sup>

Since the mode of anthelmintic action appears to be the inhibition of glucose uptake and glycogen breakdown it is of interest to note that there have been no effects of FBZ on blood glucose levels of the

host.<sup>37,d</sup> The carbamate moiety of this anthelmintic has not produced a decrease in cholinesterase activity.<sup>37,d</sup>

Acute toxicity studies in sheep fed single doses of 75 mg FBZ/kg have shown an increase in SGOT, alkaline phosphatase, GDH and SDH for 3 days post-dosing. Higher levels of 500, 1600 or 5000 mg FBZ/kg have been associated with increases in SGOT, SGPT, GDH and SDH.<sup>c</sup> In sheep given 5, 15 or 45 mg/kg for 30 days myocardial lesions were noted in some animals in the 45 mg group. In all dose groups a dose-dependent fat free vacuolization of the liver parenchyma was noted.<sup>14</sup>

No chronic (90 days or more) studies have been reported in swine. Chronic studies with rats at doses up to 25 mg/kg have not produced any significant deviations from the parameters of normal control populations.<sup>1,14</sup> Dogs given 20, 50 or 125 mg FBZ/kg for 90 days also had no significant deviations from control values.<sup>c</sup>

#### REPRODUCTIVE TOXICITY

Unlike some other members of the benzimidazole family, FBZ has shown little reproductive toxicity.<sup>38,39,40,c</sup> Rats given daily oral doses of up to 2500 mg FBZ/kg from the 7th through 16th day of gestation had fetuses with no intrauterine developmental damage.<sup>c</sup> In sheep treated orally with 15 mg FBZ/kg 4 times at 3-week intervals during various stages of pregnancy, no reproductive effects were found.<sup>c</sup> No evidence of FBZ-induced teratogenicity has been found in any of the species in which FBZ has been tested.<sup>38,39,40,41</sup> However, one of the metabolites of FBZ, a sulfoxide found in the milk of cows treated with FBZ, is teratogenic in the rat and sheep.<sup>42</sup>

---

<sup>d</sup>Booze T, Oehme F: Safety evaluation of fenbendazole in swine. Unpublished data, 1980.

The offspring of rabbits given daily oral doses of 10, 25 or 63 mg FBZ/kg from the 7th to the 19th day of gestation had decreased survivability in the 63 mg group when compared to the control group. No abnormalities were noted at the various stages of fetal development.<sup>c</sup>

Rams dosed once with 50 mg FBZ/kg or once a month for 4 months with 15 mg FBZ/kg had no significant variations or abnormalities in semen.<sup>c</sup> Ewes undergoing the same dosage regimen had no decreased fertility or other reproductive functions.<sup>c</sup>

Twenty-four stallions ranging in age from 2-16 years given single oral doses of 20 mg FBZ/kg failed to show any significant effects on semen, testes, spermatogenesis or testosterone level.<sup>c</sup> Pregnant mares given single doses of 10 mg/kg or 25 mg FBZ/kg, produced foals free from abnormalities born 1 to 121 days after treatment.<sup>c</sup>

#### MISCELLANEOUS SAFETY STUDIES

Administration of 10 mg FBZ/kg into the trachea of sheep produced slightly elevated temperatures, increased respiratory frequencies and spontaneous cough for 2-3 days post-dosing. All signs disappeared without treatment. The recommended dose (5 mg FBZ/kg) did not produce any clinical effects.<sup>14</sup>

Fenbendazole was found to have no effects on motor activity, hexobarbitone anesthesia, pain perception or convulsive activity in mice.<sup>c</sup>

No anti-inflammatory, inflammatory, pyretic, anti-pyretic or diuretic activity was produced in rats receiving FBZ.<sup>c</sup>

Five human males were given a dose of 3.8 mg FBZ/kg after breakfast and neither subjective nor objective side effects could be determined. The same held true for 6 males given 7.5 mg FBZ/kg 12 hours after a meal.<sup>c</sup>

KANSAS STATE UNIVERSITY  
Manhattan, Kansas

1981

#### ABSTRACT

Thirty 25-kg female pigs were given fenbendazole (FBZ) in feed for 3 days to test the safety of the drug. The doses used were 0, 3, 9, 15 and 25 mg FBZ active ingredient/kg of body weight. Blood and urine were collected every other day 10 days prior to, 3 days during, and 10 days after dosing. Blood chemistry, hematology and urinalysis were evaluated. All pigs were sacrificed on day +13 following initiation of dosing, and gross and microscopic pathology examinations were performed. Bone marrow cytology was determined.

There were no significant differences between groups in any of the values measured during any phase of the experiment. This study indicated no significant drug-related effects in physical observation, blood chemistry, hematology, urinalysis, gross and microscopic pathology, or bone marrow cytology when FBZ was administered to pigs at doses of up to 25 mg/kg for 3 days.
