## 2002 WHEAT CROP REVIEW

### Crop Development

The 2002 wheat crop started off ahead of last year's pace with over 90% emerged by late October. Over 70% of the crop was in good or excellent condition through early November. However, the condition of the crop deteriorated steadily from November through April in response to below-normal precipitation, especially in western Kansas. By early June, 80% of the acres were rated as fair to very poor. Many of the spring rains were too late to be of much benefit to a crop that had been subjected to moisture stress all winter. From November through April, 70%-80% of the crop acres were rated as being short or very short of topsoil moisture. Much of the dryland wheat in western Kansas never developed an adequate root system and wasn't able to take advantage of the limited spring rainfall. Fields that had good moisture conservation techniques applied did better than might otherwise have been expected.

Jointing started quickly, but soon lagged behind average. Heading tracked fairly closely with previous years. Western areas had to contend with scattered freeze damage in late May. Warm conditions in late May and early June hastened maturation so that the wheat ripened ahead of average. Heavy rains in southeast Kansas delayed harvest to some extent, increased diseases, and reduced grain quality. Several areas suffered considerable damage from hail. Hot, dry weather in late June enabled rapid completion of harvest after a slow start. Nearly 60% of the crop was harvested during the last week of June. (From *Crop-Weather* reports, Kansas Ag. Statistics, and Mary Knapp, KSU State Climatologist).

**Figure 1. May precipitation distribution.**

### Diseases

Diseases began to appear last fall. Low infestations of speckled leaf blotch, leaf rust, and wheat streak mosaic occasionally were found in the central third of the state by early November. Crazy top was found in low-lying areas in some fields. By mid-November, these diseases were found in southwest Kansas, especially in early, irrigated fields.

Dry conditions in early spring limited disease development. Low levels of speckled leaf blotch were observed in central Kansas in early April. Powdery mildew was seen in several fields in southeast Kansas, occasionally at a moderate level. Light levels of *Septoria nodorum* leaf blight were found in

some southern fields. Soil borne mosaic was identified in southeast Kansas. Spindle streak and barley yellow dwarf were confirmed in central and eastern Kansas, respectively.

By mid-May, tan spot and leaf rust had advanced to the flag leaf in southern fields, but incidences were relatively low. Barley yellow dwarf and wheat streak mosaic were reported at moderate levels in south central and central wheat fields. Foliar disease remained low in the west, northeast, and north-central regions. Other diseases included powdery mildew, one case of strawbreaker, dryland foot rot in south-central Kansas, loose smut in south-central and central Kansas, speckled leaf blotch in central, southeast, and east-central Kansas, and some stripe rust in south-central Kansas.

May rains allowed foliar diseases to increase. Tan spot, barley yellow dwarf, and leaf rust were common on flag leaves in central and southeast Kansas by late May. In some fields, all leaves were lost to disease. Take all, dryland foot rot, scab, and bunt were seen in extreme southern counties. (Kansas Department of Agriculture Plant Disease Reports).

### Insects

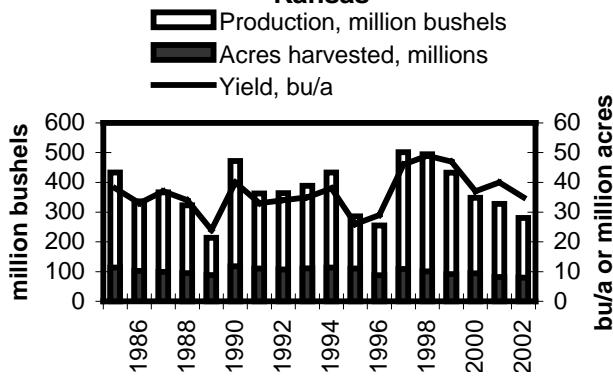

Significant fall insect activity involved oat birdcherry aphids and greenbugs. The winter grain mite and army cutworm occasionally were found in south-central fields. Chinch bugs damaged some fields after sorghum, sudan, or wheat.

Spring insect activity was fairly limited. Small numbers of army cutworm were found in about the western half of the state in early March; however, damage developed in some south-central fields. Considerable acreages were treated in March in parts of Reno, Sumner, and Harper counties. Lack of moisture slowed recovery in some of those treated fields. Only trace numbers of Russian wheat aphid were found in a small number of southwest Kansas fields. (From Kansas Department of Agriculture Cooperative Economic Insect Reports and Extension Entomologist, Leroy Brooks).

### Harvest Statistics

The Kansas Agricultural Statistics' July 11 estimate of the 2002 crop was 272.0 million bushels from 8.0 million acres. That is the lowest harvested acreage since 1957. This continues the 5-year decline in total production since the 1997 crop of close to 500 million bushels. (From July 11, 2002 *CROPS* report, Kansas Ag. Statistics, Topeka).

**Figure 2. Historical wheat production in Kansas**

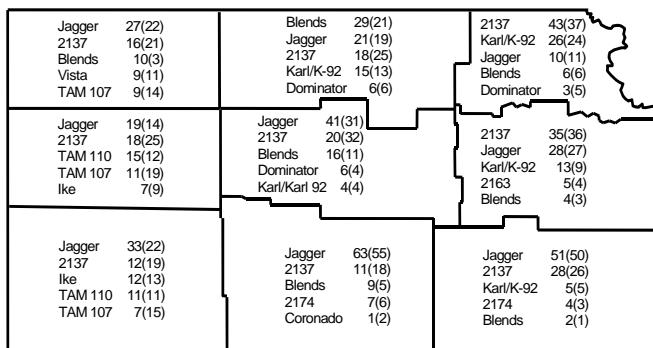

## Acreage Distribution

The top five varieties occupied 68.0% of the state's seeded acreage in 2002. Including the blends as a single variety increased that to 76.4%. (From February 12, 2001, *Wheat Variety* report, Kansas Ag. Statistics, Topeka).

**Figure 3. Leading wheat varieties in Kansas**

Percent of seeded acreage for 2002 and (2001) crops

## 2002 PERFORMANCE TESTS

### Objectives

To help Kansas growers select wheat varieties suited for their area and conditions, the Kansas Agricultural Experiment Station annually compares both new and currently grown varieties in the state's major crop-producing areas. These tests provide Kansas growers with unbiased performance information on varieties available in the state.

### Varieties Included in Tests

Public varieties are selected for inclusion in the tests based on several criteria. Most represent new or established varieties with potential for successful use in Kansas. Some are included as long-term checks. Others are entered at the request of the originating institution.

Originators or marketers enter privately developed varieties on a voluntary basis. Entrants choose both the entries and test sites and pay a fee to help defray test expenses. The 2002 private entrants are listed in Table 1. Twelve entrants provided a total of 41 varieties for testing.

Table 15 describes the characteristics of seed submitted for testing. Seed quality, including such factors as size, purity, and germination, can be important in determining the performance of a variety. Wheat seed used for entries in the Kansas Crop Performance Tests is prepared professionally and usually meets or exceeds Kansas Crop Improvement Certification standards. Performance of a given variety or hybrid comparable to that obtained in these tests is best assured under similar environmental and cultural conditions and with the use of certified or professionally prepared seed.

### Environmental Factors Affecting Tests

Locations of test sites are shown on the map on the front cover. Five locations had to be abandoned because of drought or hail. The western locations were affected by extremely dry, stressful conditions, significantly affecting

test results. Site descriptions and management practices for each site are summarized in Table 3 on page 4.

### Test Results and Variety Characterization

Results from Kansas tests are presented in Tables 4 through 14. The information in these tables is from replicated comparisons at several sites located across the state.

Yields are reported as bushels per acre (60 pounds per bushel) adjusted to a moisture content of 13%, where moistures were reported at harvest. Yields also are converted to percentages of the test average to speed recognition of highest yielding entries. Multi-year averages are presented for those varieties entered more than one year. One-year or one-location results can be misleading because of the possibility of unusual weather or pest conditions.

Additional information such as test weight, heading date, and plant height is helpful for fine-tuning variety comparisons. For example, a relatively tall variety may yield well in the tests, but may not be appropriate for some situations. Conversely, some producers may want a tall variety for a variety of reasons. Planting varieties with a range of maturities helps minimize weather risks.

At the bottom of each table is the LSD (least significant difference) for each column of replicated data. One can think of the LSD as a "margin of error" that shows how big the difference between two varieties must be for it to be significant. The use of the LSD is intended to reduce the chance of overemphasizing small differences. Small variations in soil structure, fertility, water-holding characteristics, and other test-site characteristics can cause considerable yield variation among plots of the same variety grown only a short distance apart.

Coleoptile length (Table 15) measurements predict the relative ability of a cultivar to emerge from deep plantings through noncrusted soil. Maximum coleoptile elongation of a variety is influenced heavily by soil temperature. If deep planting is needed because of dry soil late in the planting season, choice of variety will have minimal effects on stand establishment. The same can be said for plantings made during optimum times when soil temperature is already below 65° F. Plantings made in late August or early September when soil temperature is high will be the most vulnerable to poor emergence because of coleoptile length. If plantings must be made deeper than 3.5 in. when soil temperature is high, use a variety that has a long coleoptile.

### Graphical Performance Summaries

Figures 4-8 summarize the performance of each variety standardized to the average of two check varieties: Jagger and 2137. These were the most popular varieties in 2002 with 58.3% of the total wheat acreage in Kansas. The number of direct comparisons of a given variety with the check varieties has a bearing on the confidence one can place in the performance of that variety. The number beside each bar shows the number of times that variety was compared to the check varieties. In general, the more comparisons, the greater confidence one has in a value.

**Table 2. Comparisons of leading winter wheat varieties - agronomy & quality**

Scale: 1=Best 1=Best 1=Early 1=Short 1=Long 1=Best 1=Best 1=Best 1=Best

<sup>1</sup> Coleoptile length measured at 75 degrees F, which is the average soil temperature at 4" in western Kansas on September 1. Coleoptile rating of 3 is long and is equal to about 4.2", a rating of 8 is short and is equal to about 2.4". See discussion of coleoptile length on page 2. Ratings provided by T. Joe Martin, Kansas State University Agricultural Research Center - Hays.

<sup>2</sup> Hessian fly ratings by E. Parker, USDA; S = majority of plants susceptible, H = mixture of susceptible and resistant plants (heterogenous), R = majority of plants resistant. Tested with the Great Plains Hessian fly.

**Excerpts from the UNIVERSITY RESEARCH POLICY AGREEMENT  
WITH COOPERATING SEED COMPANIES\***

Permission is hereby given to Kansas State University to test varieties and/or hybrids designated on the attached entry forms in the manner indicated in the test announcements. I certify that seed submitted for testing is a true sample of the seed being offered for sale.

I understand that all results from Kansas Crop Performance Tests belong to the University and the public and shall be controlled by the University so as to produce the greatest benefit to the public. Performance data may be used in the following ways: 1) Tables may be reproduced in their entirety provided the source is referenced and data are not manipulated or reinterpreted; 2) Advertising statements by an individual company about the performance of its entries may be made as long as they are accurate statements about the data as published, with no reference to other companies' names or cultivars. In both cases, the following must be included with the reprint or ad citing the appropriate publication number and title: "See the official Kansas State University Agricultural Experiment Station and Cooperative Extension Service Report of Progress 896 '2002 Kansas Performance Tests with Wheat Varieties', or the Kansas Crop Performance Test website, <http://www.ksu.edu/kscpt>, for details. Endorsement or recommendation by Kansas State University is not implied."
