1995 KANSAS GRAIN AND FORAGE SORGHUM PERFORMANCE TESTS

INTRODUCTION

TEST OBJECTIVES AND PROCEDURES

Sorghum Performance Tests, conducted annually by the Kansas Agricultural Experiment Station, provide farmers, extension workers, and private research and sales personnel with unbiased agronomic information on many of the sorghum hybrids marketed in the state. Entry fees from private seed companies partially finance performance tests. Seed companies receive test announcements and entry forms in late January each year; deadlines for receipt of completed entry forms and seed are in early March. Because entry selection and location are voluntary, not all hybrids grown in the state are included in tests, and the same hybrids are not grown at all test locations.

Individual test discussions include summaries of growing-season weather data for each location. These data are from the nearest weather-reporting station, often supplemented with information from the test site. Precipitation graphs include cumulative lines for 1995 and the 30-year normal and the daily rainfall amounts since last fall. Temperature graphs include daily maximum and minimum temperatures compared with normal. Growing degree graphs include cumulative lines for 1995 and normal. All graphs include vertical lines denoting planting, heading, and harvest dates if available. The graphs reveal general trends in precipitation compared to normal. For more detailed information, a small table presents monthly totals and averages for the growing season. Comparisons of the current year's weather with long-time averages often help explain unusual plant development patterns and inconsistent performance of individual hybrids over years.

Explanatory information for each test precedes data summaries. Tables 16 and 17 include yield

summaries expressed as percent of the test average for the 1995 growing season. The Appendices include listings of the 1995 entrants, entries, and hybrid characteristics provided by the entrants.

Beginning in 1995, tests were planted at a rate 20-30% above the desired populations with only minimal thinning to remove doubles several weeks after planting. Planting to stand includes hybrid differences in stand establishment and early-season vigor in the overall performance evaluation. These differences may or may not be genetically controlled, but contribute to marketed product performance in either case. As such, they should be included in performance comparisons.

Two-row, tractor-powered, modified, White air-planters were used for nearly all tests. Except for three locations, each test included three plots (replications) of each hybrid in a randomized complete block design. Each harvested plot consisted of two rows trimmed to a specific length ranging from 20 to 45 feet. Tests planted in Riley, Chase, and Stafford counties contained four replications of each entry. Agronomists used Gleaner-E combines equipped with electronic weighing and sampling devices to harvest most tests. Forage sorghum tests were harvested with modified tractor-mounted, one-row, forage choppers. Subsamples were harvested for grain yield estimates in the Reno and Ellis County forage sorghum tests.

Results for each test include *GRAIN YIELDS* reported as bushels per acre of shelled grain (56 lbs/bu) adjusted to a moisture content of 12.5%. *YIELDS* are converted also to *YIELD AS PERCENTAGE OF TEST AVERAGE* to speed recognition of high-yielding hybrids. Hybrids yielding more than the test average year after year merit consideration, but adaptation to

individual farms for appropriate maturity, stalk strength, and other factors also must be considered.

Forage sorghum test results include *SILAGE YIELDS* reported as tons of whole-plant silage adjusted to 70% moisture. Grain yields for the forage sorghum tests are reported as bushels per acre where grain yields were available.

When appropriate, tables include the number of *LODGED* stalks. Both broken stalks and stalks leaning more than 45 degrees from vertical were considered lodged, although most were harvestable with modern machinery.

Two characteristics contributed to estimations of relative maturity at most locations. *DAYS TO HALF BLOOM* is the number of days between planting and the date when half of the heads of a given hybrid have some florets in bloom. *GRAIN MOISTURE* at harvest also may help categorize hybrids for relative maturity, when harvest is early enough to provide a range in moisture contents among entries.

Beginning in 1993, entries were grouped with hybrids of similar maturity. All entries were classified as Early, Medium, or Late hybrids based on information provided by the entrant or on past performance in Kansas tests. Hybrid comparisons in 1995 tests are valid within and across maturity groupings by using the appropriate least significant difference (L.S.D.). L.S.D.'s for comparing hybrids within a group are listed at the bottom of that group. L.S.D.'s for comparing hybrids in different groups are listed at the bottom of the table. In tables 1-15, hybrids are listed in order of ascending moisture and in order of ascending bloom date within a given moisture level.

The *GROWTH UNIT* or *GROWING DEGREE DAY* concept, as developed for corn, may be used for sorghum to measure the amount of heat available for growth and maturity. The formula used to generate the growing degree days in individual test discussions is as follows: Take the maximum temperature plus the minimum temperature for each day, divide by 2, and then subtract a base temperature of about 34 (actually 1 C was used in the calculations). The purpose is

to describe temperatures for the season for comparison with previous years and other locations in explaining relative rates of plant development. Research by Dr. Richard Vanderlip and his students at Kansas State University has indicated an excellent relationship between the growth units generated by these calculations and the actual rate of plant development from blooming to physiological maturity.

Small differences in yield or other characteristics should not be overemphasized. Performance test tables include least significant differences (L.S.D.'s) at the bottom of each column. Unless two entries differ by at least the L.S.D. shown, little confidence can be placed in one being superior to the other. The coefficient of variability (C.V.) can be used to estimate the degree of confidence one can have in published data from replicated tests. For yield estimates in this testing program, C.V.'s below 10% generally indicate reliable, uniform data, whereas C.V.'s of 10 to 15% are common and usually indicate that data are acceptable for the rough performance comparisons desired from these tests. Tests with C.V.'s over 15% still may be useful, but hybrid comparisons lack precision.

All but one of the 1995 grain sorghum tests provided results that could be included in this report. Accurate results were not obtained from the Greeley County irrigated sorghum test because of damage from summer hail storms and the late September freeze. Examine introductory information for each test location carefully.

1995 STATEWIDE GROWING CONDITIONS

The 1995 sorghum crop developed behind the average schedule, especially early in the season. Most of the planting was delayed until mid to late June. In early June, only 5% of the acres were planted, compared to 72% in 1994 and the average of 45%. Planting was not complete until mid-July. Heading began in late July in southeast and south central Kansas. Heading was 10% in early August, which was 24% behind the 5-year average. By mid-August, only 56% of the crop had headed and only 1% had begun to color. At the time of the early freeze in late September,

only 14% of the acreage was considered mature, compared to the average of 37%.

Harvest was not fully under way until mid-October, but made good progress in late October. By mid-October, 28% of the crop was out of the field. By that time last year, 68% of the crop was harvested. By early November, 93% of the crop had been harvested. Harvest was not fully complete at this writing. High winds in October contributed to lodging, especially in fields already subjected to borer damage and stalk rots.

The condition of the 1995 crop was generally worse than that of the 1994 crop for the entire growing season. Early in the season, Kansas Agricultural Statistics reports rated 42% of the crop as fair, poor, or very poor. However, by early August, only 21% of the crop was in those categories. By mid-October, 57% of the crop was again in the fair or worse categories, likely because of the effects of the September freeze.

(From **Crop-Weather** reports, Kansas Agricultural Statistics, Topeka.)

The late planting and cool spring temperatures seemed to disrupt normal development of insect populations. In mid-May, high numbers of black cutworm moths were caught, indicating a potential problem, but they did not cause major damage aside from a few localized areas. The late-planted sorghum might have been attractive for chinch bugs, but wet wheat straw seemed to delay migration enough so that treatment for chinch bugs was not widespread. Fall armyworm and corn earworm larvae caused leaf damage over a wide area of eastern Kansas by feeding in whorls of young sorghum, but long-term effects on the plants were minimal. Some very late sorghum in south central Kansas experienced devastating damage from fall armyworms, with some plants destroyed to ground level in late August. Treatment for greenbugs was common in the southwest in early September. Entomologists found various types of head worms (corn earworm, fall armyworm, sorghum webworm) feeding on sorghum heads during September, but treatment for these pests was cut off after the September 22 freeze.

(Insect information from **Cooperative Economic Insect Survey Report**, Kansas State Board of Agriculture.)

Although the usual set of disease was found in Kansas this year, disease levels were generally lower than normal. Some sooty stripe was found in the eastern two thirds of the state in August and September, but levels were typically low. Thickened and stunted plant tops, characteristic of crazy top, were seen throughout the state. In early September, western and eastern fields had low levels of various diseases (bacterial streak, bacterial stripe, bacterial top rot, downy mildew, leaf blight), but central fields were very healthy. Leaf blight was common in eastern fields, but bacterial streak was more common in western fields. Zonate leaf spot, gray leaf spot, and rough spot typically were found only in southeastern fields.

(Disease information from **Plant Disease Survey Report**, Kansas State Board of Agriculture.)

The projected crop of 165.3 million bushels, although 28% lower than last year's crop and the smallest Kansas crop since 1983, enabled Kansas to maintain its position as the top grain sorghum-producing state. The 1995 production was from 3% fewer acres (2.9 million) than were harvested last year. The average yield of 57 bushels per acre is 20 bushels lower than that in 1994.

(From November 9 **Crops** report, Kansas Agricultural Statistics, Topeka.)

ACKNOWLEDGMENTS

Cooperation of Research Center and Experiment Field personnel who furnished land and performed many or all of the field operations is sincerely appreciated. Technician Edward O. Quigley packaged seed and performed field operations for some of the tests. Technician James R. Cochran also performed many lab and field operations in addition to generating electronic versions of the publication and assisting with data summarization. Student workers Justin Geering and Darrin Holle helped with seed counting, sign painting, and plot maintenance. Mary Knapp of the Weather Data Library provided much of the climatological information.

NORTHEASTERN KANSAS ON SILTY CLAY LOAM SOIL

LOCATION: Cornbelt Experiment Field
9 miles southwest of Hiawatha in **Brown County**

COOPERATORS: Brian Marsh, agronomist
Steve Milne and David Zeit, technicians

TEST SITE: Grundy silty clay loam
Soybeans in 1994 and grain sorghum in 1993

FERTILIZATION: 100 lbs N/acre preplant

PLANTING DATE: June 15

HARVEST DATE: October 19

PEST CONTROL: Good
Furadan in furrow at planting
Ramrod/Atrazine at planting

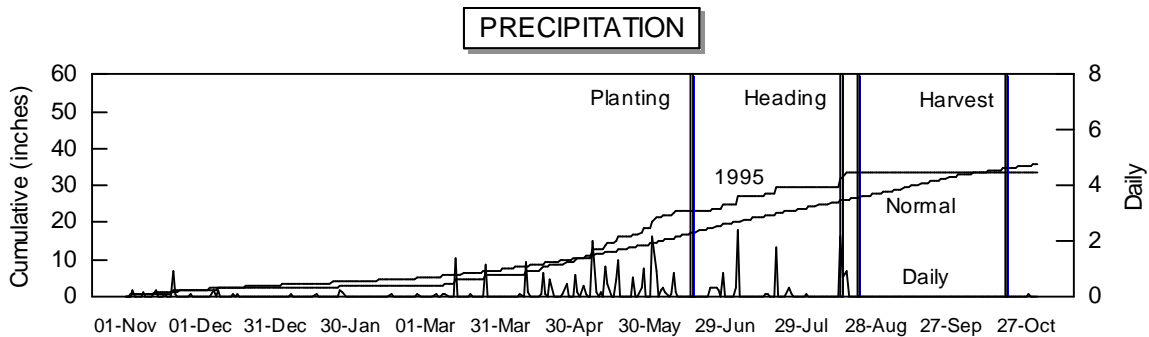

POPULATION: 35,000 plants/acre, 6 in. spacing

1995 GROWING CONDITIONS:

Wet, cool conditions in April and May delayed planting. Germination was uneven and resulted in relatively poor stands. Profuse tillering helped plants overcome the low stands to a large extent. A freeze on September 22 injured immature heads, especially those on later-developing tillers. The freeze also slowed grain drying, forcing harvest at a high moisture content.

1995 GROWING CONDITIONS:

Wet weather conditions delayed planting until late June. The resulting stands were less than desired, but tillering helped to minimize the effects of the low stands. The late planting carried through to a late harvest. Grain moisture was still relatively high at harvest in early November. The late harvest resulted in some lodging. Severe lodging likely contributed to lower yields in several entries.

* L.S.D. for comparing hybrids within a maturity grouping.

** L.S.D. for comparing hybrids in different maturity groups.

Unless two varieties differ by more than the L.S.D., little confidence can be placed in one being superior to the other.

EAST CENTRAL KANSAS ON SILTY CLAY SOIL

LOCATION: ImMasche Research Center
East of Strong City in **Chase County**

COOPERATORS: Kraig Roozeboom, agronomist
Gene Eidman, tenant

TEST SITE: Osage silty clay
Soybeans in 1994; soybeans 1993

FERTILIZATION: 50 lbs N/acre preplant
32 lbs N/acre at planting

PLANTING DATE: June 19

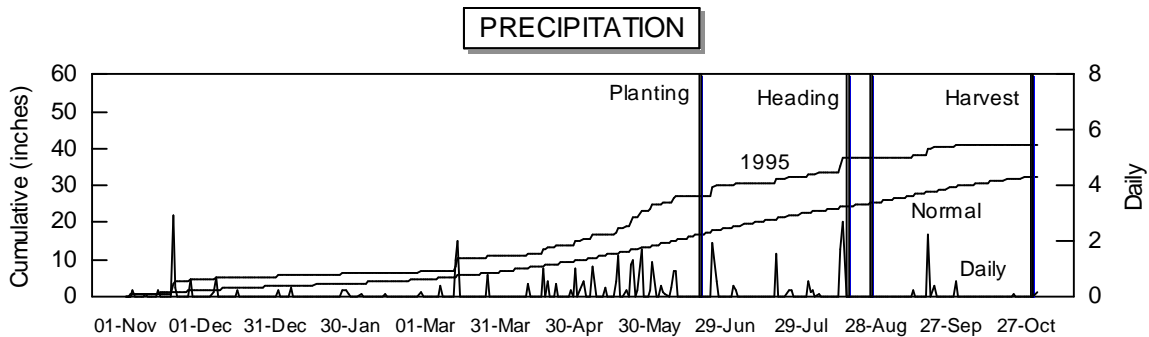

HARVEST DATE: October 29

PEST CONTROL:
Ramrod/Atrazine at planting, hand weeding later in the season, near heading time

POPULATION: 35,000 plants/acre, 6 in. spacing

BLOOM DATES:	--	8/17-8/22	8/18-8/26	8/17-8/26

1995 GROWING CONDITIONS:
Wet conditions delayed planting much beyond the optimum date for this location. Cool temperatures in early July caused plants to get off to a slow start. Very warm temperatures in late July and August helped move things along, but most hybrids were not fully mature by the late-September freeze. Dry-down was very slow after the freeze, delaying harvest until late October.

1995 GROWING CONDITIONS:

The wet spring weather delayed planting until late June. Temperatures in July, August, and early September often exceeded 90°F, helping to speed maturity. Cool temperatures in late September did not kill plants but slowed further grain development. A late infestation of corn earworm and fall armyworm after flowering was controlled with Lorsban and caused little damage. Fusarium stalk rot resulted in some lodging, especially for the early maturing hybrids.

* L.S.D. for comparing hybrids within a maturity grouping.

** L.S.D. for comparing hybrids in different maturity groups.

Unless two varieties differ by more than the L.S.D., little confidence can be placed in one being superior to the other.

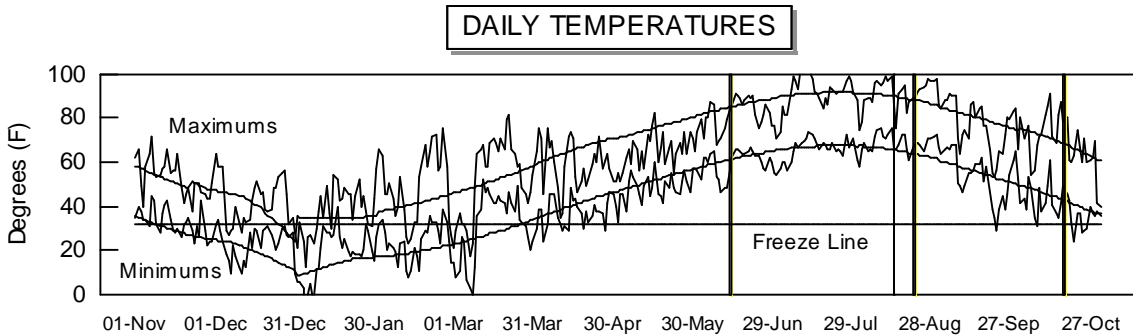

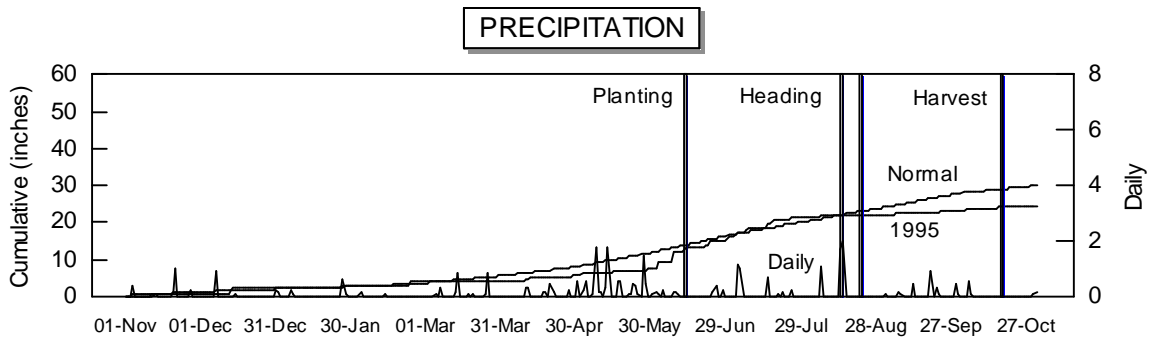

NORTH CENTRAL KANSAS ON SILT LOAM SOIL

LOCATION: North Central Kansas Experiment Field
West of Belleville in **Republic County**
COOPERATORS: Barney Gordon, agronomist
Michael Larson and Allan Milner, technicians
TEST SITE: Crete silt loam
Wheat in 1994 and oats in 1993
FERTILIZATION: 120 lbs N/acre preplant
30 lbs P₂O₅/acre at planting
PLANTING DATE: June 13
HARVEST DATE: October 17
PEST CONTROL: Good
POPULATION: 35,000 plants/acre, 6 in. spacing

	EARLY	MEDIUM	LATE	ALL
STAND (%):	98	101	98	99

BLOOM DATES:	8/14-17	8/14-8/20	8/18-8/22	7/23-8/2

1995 GROWING CONDITIONS:

A very wet May delayed planting until mid-June.
Very hot weather conditions prevailed in mid-July.
Diseases and insects caused little or no damage of importance. Yields were quite good, considering the shortened growing season.

1995 GROWING CONDITIONS:
Excellent soil moisture at planting resulted in good stands. However, June-August precipitation was the lowest on record. None of the summer rain was usable by the crop, because it fell in such small amounts. Subsoil moisture obviously enabled the production of reasonable yields, considering the growing conditions. Head smut developed on some entries.

1995 GROWING CONDITIONS:

An excellent seedbed and warm temperatures at planting resulted in rapid emergence. Heavy rainfall occurred for an extended period in the spring prior to planting and during the first half of August. Dry conditions prevailed from late June through mid-July and from mid-August through mid-September. Dry conditions in late summer favored development of stalk rots and lodging. An early frost on September 22 also affected yields.

BLOOM DATES: 8/8-8/14 8/10-8/18 8/14-8/19 8/8-8/19

1995 GROWING CONDITIONS:
Wet, cool conditions in May and June delayed planting. Generally hot and dry conditions in late July, August, and early September likely contributed to stalk rots and lodging. Stalks were beginning to lodge already in mid September.

1995 GROWING CONDITIONS:
Cool, wet spring weather conditions delayed planting. Summer weather was hot and dry, with sporadic rains providing enough moisture to produce a respectable dryland crop for this site. Borer damage and stalk rots caused some lodging, and high winds late in the season added to the problem. The early freeze and snow in September did not appear to damage the crop as much as originally feared but likely caused the variable yields among the late hybrids.

1995 GROWING CONDITIONS:

Cool, wet weather conditions in spring delayed planting and slowed early growth. Weather conditions changed to hot, dry, and windy in the first week of July. A cold front on September 22 brought freezing temperatures and 5 inches of snow, ending the growing season. Only early-maturing entries were mature at that time. Greenbugs were present in high numbers very late in the season but likely had little influence on yields.

BLOOM DATES:	8/15-8/25	8/15-9/1	--	8/15-9/1

1995 GROWING CONDITIONS:

Yields for this test were respectable, considering the shortened, relatively cool, growing season. Warm temperatures in July and August helped make up for cool temperatures earlier in the season, but an early freeze and subsequent cool temperatures prevented full maturation of many entries.

BLOOM DATES:	8/13-8/22	8/15-8/24	--	8/13-8/24

1995 GROWING CONDITIONS:
Emergence and resulting stands were excellent. Plants got off to a slow start because of cool, wet weather well into June. August was very hot and dry, with daily maximum temperatures 5°F above normal. The grain filling period was shortened on both ends by the slow start and the early freeze on September 22.

* L.S.D. for comparing hybrids within a maturity grouping.

** L.S.D. for comparing hybrids in different maturity groups.

Unless two varieties differ by more than the L.S.D., little confidence can be placed in one being superior to the other.

SOUTHWESTERN KANSAS IRRIGATED

LOCATION: Southwest Research-Extension Center
Near Garden City in **Finney County**

COOPERATORS: Merle Witt, agronomist

TEST SITE: Keith silt loam

Fallow in 1994 and grain sorghum in 1993

FERTILIZATION: 150 lbs N/acre preplant

PLANTING DATE: June 9

HARVEST DATE: October 25

PEST CONTROL: Sprayed to control greenbugs on
Sept. 1

POPULATION: 70,000 plants/acre, 3 in. spacing

EARLY MEDIUM LATE ALL

TEST YIELDS:

Avg. (bu/a):	--	82	76	79
Range (bu/a):	--	67-99	57-102	57-102
L.S.D. (bu/a):	--	15.7	17.0	17.7
C.V. (%):	--	13.9	13.0	13.8

BLOOM DATES: -- 8/10-8/21 8/18-8/25 8/10-8/25

IRRIGATION: 5 inches applied on each date:
7/12 and 8/10

1995 GROWING CONDITIONS:

Emergence and resulting stands were excellent. Plants got off to a slow start because of cool, wet weather well into June. August was very hot and dry, with daily maximum temperatures 5°F above normal. The grain filling period was shortened on both ends by the slow start and the early freeze on September 22.

GROWING-SEASON WEATHER SUMMARY

* L.S.D. for comparing hybrids within a maturity grouping. ** L.S.D. for comparing hybrids in different maturity groups.

Unless two varieties differ by more than the L.S.D., little confidence can be placed in one being superior to the other.

¹Silage yields adjusted to 70% moisture. ²Grain yields estimated from 10 hand-harvested heads and adjusted to 12.5% moisture.

FORAGE SORGHUM
SOUTHWEST KANSAS, IRRIGATED
LOCATION: Southwest Research-Extension Center
Near Garden City in **Finney County**
TEST SITE: Keith silt loam, sorghum-94, fallow-93
FERTILIZATION: 200 lbs N/acre preplant
PLANTING DATE: June 7
HARVEST DATE: Sept. 29
PEST CONTROL: Good

POPULATION: 70,000 plants/acre, 3 in. spacing
EARLY MEDIUM LATE ALL
SILAGE YIELDS:
Avg. (tons/a): 21.9 20.8 23.9 22.4
Range (tons/a): 18-26 17-23 19-27 17-27
L.S.D. (tons/a): 4.5 2.6 NS 5.4
C.V. (%): 14.2 8.4 16.9 14.5
BLOOM DATES: 8/18-8/23 8/26-9/4 9/1-9/10 8/18-9/10
1995 GROWING CONDITIONS:
See weather data, graphs, etc. on page 41.

ELECTRONIC ACCESS

For those interested in accessing crop performance testing information electronically, try visiting our World Wide Web site. Most of the information contained in this publication is available for viewing or down loading. For now, the URL is <http://www.ksu.edu/~kscpt>. It may change in the future, but if it does, you still should be able to find it from the main KSU page.

Excerpts from the **UNIVERSITY RESEARCH POLICY AGREEMENT WITH COOPERATING SEED COMPANIES***

Permission is hereby given to Kansas State University to test our varieties and/or hybrids designated on the attached entry forms in the manner indicated on the test announcement. I understand that all results from Kansas crop performance tests belong to the University and to the public and shall be controlled by the University so as to produce the greatest benefit to the public. It is further agreed that the name of the University shall not be used by the company in any commercial advertising either in regard to this agreement or any other related matter.
