

# Implementing a HACCP plan

## Program cannot be successful without commitment from company management

by Mark Fowler

Delivering a quality product that is safe for consumers has always been a top priority for grain processors across the globe. Recently, food safety program requirements have necessitated increased attention as government regulation and customer requests have expanded to require more documentation and certification of proper food safety practices. Hazard Analysis and Critical Control Points (HACCP) programs have long been the standard for product safety requirements in the food industry. Defining and implementing a HACCP program is a challenging task, but one that can be achieved with the right commitment from company management.

The first HACCP program can be traced back to the Pillsbury Company, when, in the early 1960s, NASA wanted to source food for the space program that was 100% safe to be consumed by astronauts. This led Dr. Howard Bauman to develop a program that would expand beyond the traditional practice of sampling and testing of end products, but would monitor and control the process by which the products were produced to assure safe food.

The concept of HACCP was created to be a comprehensive program controlling the people, process, materials, environment, packaging and distribution involved in the food production process. Over the past few years, HACCP has gained more attention as the globalization of the food industry continues and consumer perceptions, concerns and expectations for safe food have increased.

### DEFINING A HACCP PROGRAM

Food safety hazards are properties or contaminants that may cause food to be unsafe for consumption and are defined in three general categories: physical, chemical or biological. One of the most important parts of defining critical control points for a HACCP program is to understand and

define non-hazards. Product quality characteristics such as protein content or moisture are not critical control points. Insect damage or the presence of most insects in grain is not a critical control point. These qualities and contaminants are not desirable in a quality product but would not cause illness or harm if consumed.

Physical hazards are defined into two classes: size and unexpected material. Size hazards are restricted to materials larger than 7 millimeters (mm) and smaller than 25 mm. Contaminants smaller than 7 mm are considered too small to be hazardous, while items larger than 25 mm are considered large enough to unlikely be placed into the mouth. In the mill, metal, glass, ceramics, wood, and brittle plastics are contaminants that should be addressed in a comprehensive program.

Chemical hazards can be naturally occurring or chemicals added either intentionally or unintentionally. Naturally occurring chemical hazards include mycotoxins that may be produced from molds that occur in the field or during storage, or any naturally occurring toxins from plant material. Intentionally added chemicals to the product may include flour additives or potential food allergens, such as soy or peanut products. Methods of monitoring, labeling and preventing the addition of ingredients to exceed beyond the maximum allowed levels is important. Non-intentional chemical contaminants range from cleaning chemicals used in the employee lunchroom to pesticides and herbicides potentially used in the production of the grain.

The third category, biological hazards, has been the focus for much of the new attention of regulations. Biological — specifically microbiological — contaminants come in several forms. Many are naturally occurring molds, yeasts and bacteria in the grain field. In the field, before the grain is harvested, the grain is exposed to insects, birds and other pests that can potentially leave behind bacteria. This is not

a new development but one that has to be included in a food safety program.

### CREATING A HACCP PROGRAM

Just to be clear, the hazards previously listed are not all critical control points for a food processing facility. An effective HACCP program for most facilities includes only two or three critical control points or CCPs. Most food safety concerns can and should be addressed by prerequisite programs. Prerequisite programs are the proactive prevention programs that minimize the potential for the finished food product to be exposed to contaminants. Prerequisite programs include, but are not limited to, sanitation and environmental monitoring, good manufacturing practices (GMPs) and integrated pest management (IPM) programs. Quality assurance programs are important prerequisite programs that may address ingredients, customer complaints and traceability requirements.

To create a new HACCP program for a facility can be an overwhelming task. One approach is to divide the task into manageable parts by evaluating, improving, and if necessary, implementing the prerequisite programs first.

There are seven principles of HACCP that must be followed when evaluating the food production process and creating a

HACCP program. These principles include:

- Conducting a hazard analysis of the process;
- Identifying critical control points;
- Establishing critical limits;
- Establishing monitoring requirements;
- Establishing a corrective action plan for deviations from the HACCP plan;
- Establishing procedures for verification of the HACCP system; and
- Having a recordkeeping system to document the HACCP system.

### IMPLEMENTING A HACCP PROGRAM

Implementing a successful HACCP program requires a team effort. The HACCP team should be a multi-disciplinary group that has a complete understanding of the process and complete control to make the necessary changes required to implement a HACCP plan.

When conducting a hazard analysis of the process, it is important to go step by step through the process and necessary to only evaluate food safety concerns. The acronym ICE is useful in the review and identification process. Does the process step:

- Introduce or intensify a hazard?

- Control or prevent a hazard?
- Eliminate or reduce a hazard?

Once the analysis is complete, identifying appropriate critical control points without identifying too many CCPs is the next challenge. Two important items to consider are: a CCP must be a process point and it must be the last opportunity to eliminate or reduce the hazard to an acceptable level. An example of a common over-identification of a CCP is magnets and metal detectors. A mill may have several magnets in the processing flow to help prevent equipment damage and improve food safety. However, only the final magnet or metal detector in the packing flow should be considered a CCP. All others are important control points and should be regularly monitored by a prerequisite sanitation or quality assurance program.

Existing regulations, customer requirements and scientific data should all

be considered when establishing critical limits and monitoring requirements for a HACCP program. Monitoring requirements must be tested through a deliberate

and the process to dispose of the contaminated product. The clarity of the corrective action plan is essential as every employee must know what to do in

sequence of observations to confirm the hazard is under control and to verify the effectiveness of the CCP in the future.

A corrective action plan for a CCP must include procedures to follow in the case of a deviation from the control limits set. This plan should also include the procedures to isolate the potentially contaminated product, investigation and correction of the cause of the deviation

the case of a deviation. Inaction or the wrong action could result in more product being contaminated and a greater loss to the company.

Verification of the individual points of the HACCP program is the most important step of the program implementation. The verification activities must be completed by a supervisor or manager in authority over the individuals con-

the employees monitoring the process and documenting the observations.

This leads us the final piece of an effective HACCP program — the recordkeeping system. Documentation for the monitoring, verification, deviations and corrective actions must be maintained as part of the program documentation. The procedures, location and guidelines for retaining both samples and records are the basic components of a recordkeeping system.

Once complete, the HACCP pro-

gram is compiled into a complete HACCP manual. The HACCP manual supports the program and is complete with all the CCPs, deviation plans,

#### MAINTAINING A HACCP PROGRAM

Once the HACCP program is complete, the task of the HACCP team is not finished. A good HACCP program is continually reviewed and improved. Once certified, the critical control points should not be changed unless significant changes to the process are made. However, as personnel on the team change, the HACCP

manual has to be updated. The HACCP manual should be a working document used in training of plant personnel as well as educating customers of the importance of food safety to the company.

The creation and implementation of a HACCP program is an enormous task but vital in the current food processing industry. By breaking the program down into manageable pieces of establishing prerequisite programs, evaluating of the critical points of the process and identifying control for critical points, the task of launching an effective plan becomes much more achievable. **WG**
