INTRODUCTION

Before developing the Lebesgue integral, there must be a basic understanding of Lebesgue measurable sets and Lebesgue measurable functions. By considering a typical term of the Riemann sum for a real-valued function $f(x)$ over an interval $[a, b]$, it can be seen that this term is a product of two numbers, the value of the function $f(x)$ at a specific point times the length of a sub-interval of the interval $[a, b]$ which contains the point. This sub-interval is obtained by partitioning the interval $[a, b]$, which is the domain of definition of the function $f(x)$.

The corresponding situation with the Lebesgue integral is not as simple. A typical term of a "Lebesgue sum" for a function $f(x)$ over an interval $[a, b]$ is again a product of two factors, but these factors are obtained quite differently. One of the factors, say $\alpha$, is a value of the function, but the value is related to a partition $P$ for the range of the function, and not a partition of the domain. The other factor, say $\beta$, is a number that represents "length" or measure of a set $E$ of all points $x$ in the domain for which $f(x)$ is between a particular pair of elements, say $(\alpha, \beta)$ of $P$. This measure is a generalization of length obtained by covering a set $E$ with a countable number of open sets. The set $E$ is not necessarily an interval. Defining the Lebesgue measure for these sets is discussed in the first part of this report.

Lebesgue measurable functions, or the functions "compatible" with Lebesgue measurable sets, are discussed in the second part.
of the report. Then the Lebesgue integral is defined for bounded Lebesgue measurable functions, and elementary properties are presented.

In the next part of the report the Lebesgue integral is compared with the Riemann integral, and it is shown that the set of all Riemann integrable functions is a proper subset of the set of all Lebesgue integrable functions on a closed interval. The Lebesgue integral is superior to the Riemann integral in the ease of finding limits relative to integration processes. The Lebesgue integral of a derivative is shown to yield the primitive for more general conditions than the Riemann integral. The last unit illustrates a weakness of the Lebesgue integral encountered when the derivative to be integrated is not required to be bounded.

**LEBESGUE MEASURABLE SETS**

The discussion will be restricted to sets that are bounded subsets of the real number line R. To define the Lebesgue measure of a set, two other numbers are defined; these numbers are the outer and inner Lebesgue measure of a set. Basic to the understanding of these two numbers is the concept of length of an open interval, which will now be defined.

**Definition 1.** The **length** of an open interval (a, b) is the number b-a.

If I = (a, b), then \( \mathcal{L}(I) \) will denote the length of I. Hence \( \mathcal{L}(I) = b-a \), whenever I = (a, b). Obviously \( \mathcal{L}(I) \) is a non-
negative number.

Another concept basic to the understanding of outer and inner Lebesgue measure is the concept of a component open interval.

**Definition 2.** Let \( G \) be any open subset of \( \mathbb{R} \). If the open interval \((e, b)\) is contained in \( G \) and its endpoints do not belong to \( G \),

\[
(e, b) \subset G, \ e \notin G, \ b \notin G,
\]

then this interval is said to be an **component open interval** or an **component of the set** \( G \).

**Example:** Let \( G = (0, 1) \cup (2, 3) \). Then \((0,1)\) and \((2, 3)\) are component open intervals of the set \( G \).

Using these two definitions, any set \( E \subset \mathbb{R} \) that is the union of a finite or denumerable number of disjoint component intervals can be assigned a number equal to the sum of the lengths of the component open intervals, if such a sum exists.

**Definition 3.** Let \( E \) be the union of a finite or denumerable number of pairwise disjoint open intervals. Associate with \( E \) the number \( L(E) \) such that if

\[
E = \bigcup_k I_k \quad (k = 1, 2, \ldots),
\]

then

\[
L(E) = \sum_k \ell(I_k) \quad (k = 1, 2, \ldots),
\]

whenever this sum exists.

A reason for the preceding definition becomes apparent upon considering the following theorem.
Theorem 1. If \( G \) is an open set of real numbers then \( G \) is the union of a finite or denumerable number of disjoint open intervals, called the component open intervals of \( G \) \([2, 73]\).\(^1\)

Proof. Associate with every \( x \in G \) an open interval \( I_x \) in the following way. Let

\[
I_x = \bigcup_{\lambda} I_{\lambda}, \quad \lambda \in A,
\]

for some indexing set \( A \), such that \( I_{\lambda} = (a_{\lambda}, b_{\lambda}) \subset G \) and \( x \in I_{\lambda} \). Let \( \lambda \) be the greatest lower bound of the \( a_{\lambda} \), and \( \mu \) be the least upper bound of the \( b_{\lambda} \). Then \( I_x = (\lambda, \mu) \). This may be seen by assuming \( y \geq \mu \) or \( y \leq \lambda \). If \( y \geq \mu \), then \( y \notin I_{\lambda} \) for any \( \lambda \in A \); or if \( y \leq \lambda \), \( y \notin I_{\lambda} \) for any \( \lambda \in A \), hence \( y \notin I_x \). Now it will be shown that if \( y \in (\lambda, \mu) \), \( y \in I_x \). If \( y \in (\lambda, \mu) \), then either \( y = x \) or \( x < y < \mu \), or \( \lambda < y < x \). If \( y = x \), then \( y \in I_x \). If \( x < y < \mu \), there is an \( \lambda \) such that \( y \in I_{\lambda} \), since \( \mu \) is the least upper bound of the \( b_{\lambda} \)'s. Also if \( \lambda < y < x \) there exists an \( \lambda \) such that \( y \in I_{\lambda} \), since \( \lambda \) is the greatest lower bound of the \( a_{\lambda} \)'s. Therefore \( y \in I_x \). Now it will be shown that if \( x \in G \) and \( y \in G \), then either \( I_x = I_y \) or \( I_x \cap I_y = \emptyset \). Suppose \( c \in I_x \cap I_y \), then \( I_x \cup I_y \) is an open interval. Since \( I_x \cup I_y \) contains \( x \), it follows that \( I_x \cup I_y \subset I_x \). Also \( I_x \cup I_y \) contains \( y \), so that \( I_x \cup I_y \subset I_y \). Therefore if \( c \in I_x \cap I_y \), \( I_y = I_x \).

---

\(^1\)Throughout the report this notation will be used: the first number indicates the number of the reference at the end of the report, and the second number indicates the page number.
Finally, any set of disjoint open intervals is finite or denumerable in number. Associate with each open interval of the set a rational number which is in the interval. Since disjoint open intervals are associated in this way with distinct rational numbers, the cardinal number of this set of open intervals does not exceed the cardinal number of the set of rational numbers, and so it is either finite or denumerable.

Since the null set $\emptyset$ is considered to be open, the number $L(G)$ associated with this set will be zero. Therefore a non-negative number $L(G)$ can be associated with every open set $G$; that is, $L(G) \geq 0$.

The definition of outer Lebesgue measure will now be given.

**Definition 4.** For every set $S$, the outer Lebesgue measure, 
$$m^*(S) = \inf \left\{ L(G) : G \supset S \right\},$$
where $G$ varies over all open sets containing $S$ [2, 154].

The following theorem can be proven for any open set $G$.

**Theorem 2.** If $G$ is an open set, then
$$m^*(G) = L(G) \quad [2, 155].$$

**Proof.** Let $H \supset G$ be an open set. Then every component of $G$ is contained in a component of $H$. Thus $L(H) \geq L(G)$. But $G \supset G$ is an open set. Hence
$$\inf \left\{ L(H) : H \supset G \right\} = L(G),$$
and
$$m^*(G) = L(G).$$
Another important property of outer Lebesgue measure will be presented before defining inner Lebesgue measure.

**Theorem 3.** Let $A$ and $B$ be bounded subsets of $\mathbb{R}$. If $A \subset B$, then

$$m_*(A) \leq m_*(B) \ [3, \ 64].$$

**Proof.** Let $S$ be a set consisting of the numbers $L(G_\alpha)$ associated with all open sets $G_\alpha$ containing $A$, where $\alpha$ belongs to an indexing set $J$. Let $T$ be a set consisting of the numbers $L(H_\beta)$ associated with all open sets $H_\beta$ containing $B$, where $\beta$ belongs to an indexing set $K$. If $E$ is an open set containing $B$, then $E$ necessarily contains $A$, since $A \subset B$. Therefore

$$T \subset S,$$

and

$$m_*(A) = \inf(S) \leq \inf(T) = m_*(B).$$

Now inner Lebesgue measure can be defined. Let $\Delta = [a, b]$ represent any bounded closed interval of $\mathbb{R}$. Let $S \subset \Delta$, and $C_\Delta(S)$ represent the complement of $S$ in the interval $\Delta$.

**Definition 5.** For every set $S$ the inner measure of $S$ is the number

$$m_*(S) = (b-a) - m_*(C_\Delta(S)) \ [4, \ 31].$$

The definition of a Lebesgue measurable set may now be given.

**Definition 6.** Let $E$ be any bounded subset of $\mathbb{R}$. The set $E$ is Lebesgue measurable if its outer and inner measures are equal; that is,
\[ m^*(E) = m^*_c(E) \begin{bmatrix} 4, 31 \end{bmatrix}. \]

The common value of these measures is called the Lebesgue measure of the set \( E \), and is denoted \( m(E) \).

Now that the definition of Lebesgue measure has been established, it is important to consider several families of sets which are actually measurable according to this definition. In order to accomplish this goal a few elementary properties are presented. The following lemma will be useful in proving these elementary properties.

**Lemma 1.** If \( I_1', I_2', \ldots, I_n' \) are a finite number of open intervals which cover \( \Delta = [a, b] \), then

\[ \sum_{k=1}^{n} \ell(I_k') \geq b - a \begin{bmatrix} 2, 155 \end{bmatrix}. \]

**Proof.** It may be assumed without loss of generality that \( I_k' \cap \Delta \neq \emptyset \), for every \( k = 1, 2, \ldots, n \). Let \( I_k' = (a_k, b_k) \), \( k = 1, 2, \ldots, n \). It may also be assumed without loss of generality that \( a \in I_1' = (a_1, b_1) \). Let \( b_1 \in I_2' \), and in general

\[ b_k \in I_{k+1}' = (a_{k+1}, b_{k+1}), \quad (k = 1, 2, \ldots, n-1) \]

where \( b < b_n \). Hence

\[ b - a < b_n - a_1 = (b_n - b_{n-1}) + \ldots + (b_2 - b_1) \]

\[ + (b_1 - a_1) \leq \sum_{k=1}^{n} (b_k - a_k), \]

and the proof is complete.

It is now possible to prove the following elementary
property for any bounded subset of a closed interval.

**Theorem 4.** For every set \( S \subset \Delta \), where \( \Delta = [a, b] \),
\[
m^*(S) + m^*(C_\Delta(S)) \geq b - a \quad \left[ 2, 155 \right].
\]

**Proof.** Let \( G \) and \( H \) be open sets such that \( S \subset G \) and \( C_\Delta(S) \subset H \).
Let \( I_1, I_2, \ldots \) be the component intervals of \( G \) and \( J_1, J_2, \ldots \) be the component intervals of \( H \). Since every \( x \in \Delta \) is either in \( S \) or \( C_\Delta(S) \), the open intervals \( I_1, I_2, \ldots, J_1, J_2, \ldots \) cover \( \Delta \). But \( \Delta \) is a closed bounded set, hence by the Borel Covering Theorem, a finite number of these intervals, say \( I_{k_1}, I_{k_2}, \ldots, I_{k_m} \) and \( J_{k_1}, J_{k_2}, \ldots, J_{k_n} \) cover \( \Delta \).

By lemma one, the sum
\[
\sum_{i=1}^{m} l(I_{k_i}) + \sum_{j=1}^{n} l(J_{k_j}) \geq b - a.
\]

But
\[
L(G) \geq \sum_{i=1}^{m} l(I_{k_i}) \quad \text{and} \quad L(H) \geq \sum_{j=1}^{n} l(J_{k_j}),
\]
hence
\[
L(G) + L(H) \geq b - a.
\]

It follows that
\[
m^*(S) + m^*(C_\Delta(S)) = \inf \{ L(G) : G \supset S \} + \inf \{ L(H) : H \supset C_\Delta(S) \}
\]
\[
= \inf \{ L(G) + L(H) : G \supset S, \ H \supset C_\Delta(S) \} \geq b - a.
\]

The following corollary relating outer and inner measure is apparent.

**Corollary 1.** For every \( S \subset \Delta \), where \( \Delta = [a, b] \),
\[
m^*(S) \geq m_*(S) \geq 0.
\]
An elementary property of Lebesgue measure will now be proved.

**Theorem 5.** A set $S \subseteq \Delta$, where $\Delta = [a, b]$, is measurable if and only if

$$m^*(S) + m^*(C_\Delta(S)) = b - a \quad [2, 156].$$

**Proof.** Assume the set $S$ is measurable. Then,

$$m^*(S) = m^*_m(S) = (b - a) - m^*(C_\Delta(S));$$

therefore

$$m^*(S) + m^*(C_\Delta(S)) = b - a.$$

Now assume

$$m^*(S) + m^*(C_\Delta(S)) = b - a.$$

Then it follows that

$$m^*(S) = (b - a) - m^*(C_\Delta(S)) = m^*_m(S),$$

and $S$ is measurable.

By combining the results of Theorem 4 and Theorem 5, the following theorems are obvious.

**Theorem 6.** A set $S \subseteq \Delta$, where $\Delta = [a, b]$, is nonmeasurable if and only if

$$m^*(S) + m^*(C_\Delta(S)) > b - a \quad [2, 156].$$

**Theorem 7.** Let $S$ be any measurable subset of the interval $\Delta = [a, b]$. Then $C_\Delta(S)$ is also measurable $[2, 156]$.

The following theorem establishes the measurability of an important family of sets.
Theorem 8. Let $S$ be a subset of the interval $\Delta = [a, b]$. If $m^*(S) = 0$, then $S$ is measurable and has measure zero \cite{2, 156}.

Proof. The proof follows immediately from the corollary to Theorem 4.

The following theorem establishes the measurability of countable sets.

Theorem 9. Every countable set $A \subset \mathbb{R}$ is Lebesgue measurable with $m(A) = 0$ \cite{4, 33}.

Proof. Let $A$ be the set of elements $e_1, e_2, \ldots, e_n, \ldots$. Given $\varepsilon > 0$, cover the elements $e_1, e_2, \ldots$ with open intervals $I_{e_1}, I_{e_2}, \ldots, I_{e_n}, \ldots$, respectively, such that

$$\ell(I_{e_n}) < \frac{\varepsilon}{2^n} \quad (n = 1, 2, \ldots).$$

Then the sum of the lengths

$$\sum_{n=1}^{\infty} \ell(I_{e_n}) < \sum_{n=1}^{\infty} \frac{\varepsilon}{2^n} = \varepsilon \sum_{n=1}^{\infty} \frac{1}{2^n} = \varepsilon \cdot 1 = \varepsilon.$$

Since $\varepsilon$ is an arbitrary positive real number, $m^*(A) = 0$.

Examples of sets which are measurable include the set of integers, the set of positive integers, the set of rational numbers, and the set of irrational numbers in the interval $(0, 1)$.

Another important family of sets is the collection of open sets. The following lemma is used to prove sets in this family are measurable.
Lemma 2. If $J_1$, $J_2$, \ldots are open intervals and the open set $G = \bigcup_{n=1}^{\infty} J_n$ has components $I_1$, $I_2$, \ldots, then

$$\sum_{n=1}^{\infty} \ell(I_n) \leq \sum_{n=1}^{\infty} \ell(J_n) \quad \text{[2, 157]}.$$ 

Proof. If $J_1$, $J_2$, \ldots are disjoint open intervals, then they are identically the components of $G$ and

$$\sum_{n=1}^{\infty} \ell(I_n) = \sum_{n=1}^{\infty} \ell(J_n).$$

Therefore assume that $J_1$, $J_2$, \ldots are not all disjoint. Then for some $J_i$, $J_j$, $i \neq j$ there exist $x_i, j$ such that

$$x_i, j \in J_i \cap J_j, \quad (i, j = 1, 2, \ldots).$$

Let

$$J'_i = \{x: x \in J_i \text{ and } x \notin J_j\}, \quad J_{i,j} = \{x: x \in J_i \cap J_j\},$$

end

$$J'_j = \{x: x \in J_j \text{ and } x \notin J_i\}.$$ 

The contribution of these sets to the sum of the components of $G$ is\(^2\)

$$\ell(J'_i) + \ell(J_{i,j}) + \ell(J'_j),$$

\(^2\)The $J'_i$ and $J'_j$ are half-open intervals of the form $(a, b]$ and $[a, b)$. The following definition of length is used for these half-open sets:

$$\ell(a, b] = b - a$$

end

$$\ell[a, b) = b - a.$$
whereas the contribution to the sum $\sum_{n=1}^{\infty} \ell(J_n)$ is

$$\ell(J_1') + \ell(J_1 j) + \ell(J_1') + \ell(J_1 j')$$

since

$$J_1 = J_1' \cup J_1 j \quad \text{and} \quad J_j = J_j' \cup J_1 j'. $$

Therefore, since all of these numbers are nonnegative, it can be seen that the contribution to $\sum_{i=1}^{\infty} \ell(J_i)$ is greater than the contribution to $\sum_{n=1}^{\infty} \ell(I_n)$. Hence

$$\sum_{n=1}^{\infty} \ell(I_n) \leq \sum_{n=1}^{\infty} \ell(J_n).$$

The following important theorem is proved.

**Theorem 10.** Every open set $G \subseteq \Delta = [a, b]$ is measurable [2, 157].

Proof. Since $G$ is open, it can be written as the union of a finite or denumerable number of component open intervals $I_k$ that are disjoint. Since the series

$$\sum_{k=1}^{\infty} \ell(I_k)$$

is convergent, for every $\epsilon > 0$, there is a number $n(\epsilon)$ such that

$$\sum_{k=n+1}^{\infty} \ell(I_k) < \frac{\epsilon}{2}$$

whenever $n > n(\epsilon)$. Since $G$ is open,

$$L(G) = \sum_{k=1}^{n} \ell(I_k) + \sum_{k=n+1}^{\infty} \ell(I_k),$$
and, by substitution,

\[ L(G) < \sum_{k=1}^{n} \ell(I_k) + \frac{\varepsilon}{2} \]

or

\[ L(G) - \frac{\varepsilon}{2} < \sum_{k=1}^{n} \ell(I_k). \]

Now let \( J_1, J_2, \ldots, J_m \) be the intervals in \( \Delta \) complementary to \( I_1, I_2, \ldots, I_n \). Also let \( J_k' (k = 1, 2, \ldots, m) \), be an open interval concentric with \( J_k \) such that

\[ \ell(J_k') = \ell(J_k) + \frac{\varepsilon}{2m}, \quad (k = 1, 2, \ldots, m). \]

Let \( H = \bigcup_{k=1}^{m} J_k' \); then \( L(H) \leq \sum_{k=1}^{m} \ell(J_k') \) by lemma 2. Since

\[ \sum_{k=1}^{m} \ell(J_k') + \sum_{k=1}^{n} \ell(I_k) = b - a, \]

it follows that

\[ \sum_{k=1}^{m} \ell(J_k') + \sum_{k=1}^{n} \ell(I_k) < (b - a) + \frac{\varepsilon}{2}. \]

Thus \( L(H) + L(G) < (b - a) + \varepsilon \), and since \( C_\Delta(G) \subseteq H \),

\[ m^*(G) + m^*(C_\Delta(G)) < (b - a) + \varepsilon. \]

Therefore, since \( \varepsilon \) is an arbitrary positive real number,

\[ m^*(G) + m^*(C_\Delta(G)) \leq b - a; \]

and, by Theorem 6, \( G \) is measurable.

Examples of open sets include open intervals, and sets composed of a finite or denumerable number of open intervals. By Theorem 1, these are the only open sets, with the exception of the null set.

Another family of sets is now proved to be measurable.
Theorem 11. Every closed set $F \subset \Delta$, $\Delta = [a, b]$, is measurable \([2, 158]\).

Proof. Since every closed set is the complement of an open set, then every closed set is measurable by Theorem 7.

Examples of closed sets include finite sets and the closed intervals. Therefore \{1, 2, 3\} and \([0, 1]\) are measurable sets. Also, any union of a finite number of closed sets is closed, and therefore measurable by Theorem 11.

In particular, the closed interval $\Delta = [a, b]$ is measurable, and it has measure $b - a$. This fact will now be established.

Theorem 12. If $\Delta$ is the closed interval $[a, b]$, then $\Delta$ is measurable and $m(\Delta) = b - a$.

Proof. Since $\Delta$ is closed, $\Delta$ is measurable by Theorem 11, and
\[
m^*(\Delta) = m_*(\Delta) = (b - a) - m^*(C_\Delta(\Delta)).
\]
But $C_\Delta(\Delta) = \emptyset$, and $m(\emptyset) = 0$, therefore
\[
m^*(\Delta) = m_*(\Delta) = (b - a) - 0 = b - a.
\]

Therefore, it can be seen that the number $b - a$ in the preceding theorem and definitions was actually the Lebesgue measure of the interval.

In order to develop the elementary properties of measurable functions and to establish the definition of the Lebesgue integral, unions and intersections of measurable sets must be considered.

Theorem 13. If a bounded set $E$ is the union of a finite or
denumerable number of measurable sets which are disjoint,
\[ E = \bigcup_{k} E_k \quad (E_k \cap E_{k'} = \emptyset, \ k \neq k'), \]
then \( E \) is measurable and
\[ m(E) = \sum_{k} m(E_k) \quad [3, 67]. \]

Proof. The proof follows from the inequalities
\[
\sum_{k} m(E_k) = \sum_{k} m^*(E_k) \leq m^*(E) \leq \sum_{k} m^*(E_k)
\]
\[ = \sum_{k} m(E_k), \]
since outer measure is countably subadditive \([3, 64]\) and the
inequality for inner measure holds \([3, 65]\).

**Theorem 14.** The union of a finite number of measurable sets
is a measurable set \([3, 67]\).

Proof. Let \( E = \bigcup_{k=1}^{n} E_k \), where each \( E_k \) is measurable. Given
\( \varepsilon > 0 \), there exists a closed set \( F_k \) and a bounded open set \( G_k \)
such that \( F_k \subset E_k \subset G_k \), and \( m(G_k) - m(F_k) < \varepsilon \). Set
\[ F = \bigcup_{k=1}^{n} F_k, \quad G = \bigcup_{k=1}^{n} G_k, \]
where \( F \) and \( G \) are closed and open sets respectively. Since
\( F \subset E \subset G \),
\[ m(F) \leq m_*(E) \leq m^*(E) \leq m(G). \]
The set \( G - F \) is open, since it can be represented in the form
\( G \cap C_G(F) \), and is therefore measurable. Since \( G \) can be repre-
sented as
\[ G = F \cup (G - F) \]
where \( F \) and \( G - F \) are disjoint measurable sets, the preceding theorem applies and

\[
m(G) = m(F) + m(G - F).
\]

Therefore

\[
m(G - F) = m(G) - m(F)
\]

and

\[
m(G_k - F_k) = m(G_k) - m(F_k).
\]

Since

\[
G - F \subset \bigcup_{k=1}^{n} (G_k - F_k),
\]

and all these sets are open, it follows that

\[
m(G - F) \leq \sum_{k=1}^{n} m(G_k - F_k),
\]

or

\[
m(G) - m(F) \leq \sum_{k=1}^{n} \left[ m(G_k) - m(F_k) \right] < \varepsilon.
\]

Therefore \( m^*(E) - m^*_K(E) \leq \varepsilon \), and \( E \) is measurable.

The analogous theorem for intersections of measurable sets is given.

**Theorem 15.** The intersection of a finite number of measurable sets is a measurable set \([3, 68]\).

**Proof.** Let \( E = \bigcap_{k=1}^{n} E_k \), where the sets \( E_k \) are measurable sets.

Let \( \Delta \) be any open interval containing all the sets \( E_k \). It can be verified that
\[ C_\Delta(E) = \bigcup_{k=1}^{n} C_\Delta(E_k). \]

The sets \( C_\Delta(E_k) \) are measurable, since the sets \( E_k \) are measurable, and by Theorem 14, \( C_\Delta(E) \) is measurable. Hence \( E \) is also measurable, since \( C_\Delta(C_\Delta(E)) = E \).

The next two theorems establish results for unions and intersections of denumerable measurable sets.

**Theorem 16.** If a bounded set \( E \) is the union of a denumerable number of measurable sets, then \( E \) is measurable [3, 69].

**Proof.** Let \( E = \bigcup_{k=1}^{\infty} E_k \). Let \( A_k (k = 1, 2, \ldots) \), be sets such that

\[ A_1 = E_1, \ A_2 = E_2 - E_1, \ldots, \ A_k = E_k - (E_1 \cup \ldots \cup E_{k-1}), \ldots, \]

then

\[ E = \bigcup_{k=1}^{\infty} A_k. \]

All these \( A_k \) are measurable and are disjoint, therefore \( E \) is measurable by Theorem 13.

**Theorem 17.** The intersection of a denumerable number of measurable sets is measurable [3, 69].

**Proof.** Let \( E = \bigcap_{k=1}^{\infty} E_k \), where all the sets \( E_k \) are measurable. Since \( E \subseteq E_1 \), \( E \) is bounded. Let \( \Delta \) be any open interval containing \( E \), and let

\[ A_k = \Delta \cap E_k. \]

Then
\[ E = \Delta \cap E = \Delta \cap \bigcap_{k=1}^{\infty} E_k = \bigcap_{k=1}^{\infty} (\Delta \cap E_k) = \bigcap_{k=1}^{\infty} A_k. \]

But

\[ C_\Delta(E) = \bigcup_{k=1}^{\infty} C_\Delta(A_k), \]

and by applying Theorem 7 and Theorem 16 this completes the proof.

One may be led to believe that all sets are measurable, or that all bounded sets are measurable. That this is not the case has been proved \[3, 76\], \[2, 165\]; in fact, it can be shown that, "Every measurable set of positive measure contains a nonmeasurable subset" \[3, 78\]. Examples are available \[1, 92\], \[4, 47\], although the choice axiom is used to construct them \[4, 50\].

**LEBESGUE MEASURABLE FUNCTIONS**

The concept of measurable functions is also basic to the understanding of the Lebesgue integral. In this part of the report measurable functions are defined, and a few elementary properties are presented.

**Definition 7.** The real-valued function \( f(x) \) is measurable in \([a, b]\) if the sets

\[ \{ x : \alpha \leq f(x) < \beta \} = E[\alpha \leq f(x) < \beta] \]

are measurable for every pair of real numbers \( \alpha, \beta \) with \( \alpha < \beta \) \[4, 67\].

Instead of the set used above, any one of the following
sets could be used:
\[ E[\alpha < f(x) < \beta], \quad E[\alpha < f(x) = \beta], \quad \text{or} \quad E[\alpha < f(x) \leq \beta] \]

The following theorem is an important consequence of this fact.

**Theorem 18.** If all sets of one of these four types are measurable, then the sets
\[ E[f(x) = \alpha] \]
are also measurable for every real number \( \alpha \) \([4, 67]\).

**Proof.** The proof follows from the fact that
\[ E[f(x) = \alpha] = \bigcap_n E[\alpha - \frac{1}{n} \leq f(x) < \alpha + \frac{1}{n}] \]
\( (n = 1, 2, \ldots) \).

The following theorem is very useful in deriving certain basic characteristics of measurable functions.

**Theorem 19.** In order that \( f(x) \) be measurable, it is necessary and sufficient that any one of the following sets is measurable for arbitrary real numbers \( \alpha \) and \( \beta \), respectively:
\[ E[\alpha \leq f(x)], \quad E[f(x) \leq \beta], \quad E[\alpha < f(x)], \quad \text{or} \quad E[f(x) < \beta] \]
\([4, 68]\).

A few elementary properties of measurable functions can now be established.

**Theorem 20.** If \( f(x) \) is measurable on a measurable set \( M \), then \( a - f(x), \quad a + f(x), \quad a \cdot f(x), \quad \text{and} \quad -f(x) \) are also measurable, for any real number \( a \) \([4, 68]\).
Proof. \(-f(x)\) can be obtained from \(a \cdot f(x)\) when \(a = -1\); also \(a - f(x) = a + (-f(x))\). Hence proofs are required only for \(a + f(x)\) and \(a \cdot f(x)\). The measurability of \(e + f(x)\) follows from

\[E[\chi \leq a + f(x)] = E[\chi - a \leq f(x)],\]

which is measurable by Theorem 19. The measurability of \(e \cdot f(x)\) can be established as follows: when \(a = 0\), \(a \cdot f(x) = 0\) is obviously measurable. For \(e > 0\), it follows that

\[E[\chi < a \cdot f(x)] = E[\frac{\chi}{a} < f(x)],\]

which is also measurable by Theorem 19. For \(e < 0\), the proof is similar.

The following theorem expresses a property peculiar to Lebesgue measure.

**Theorem 21.** If \(f(x)\) is measurable, \(|f(x)|\) is also measurable \([4, 68]\).

Proof. The proof follows from the equality

\[E[|f(x)| \geq \alpha] = E[f(x) \geq \alpha] \cup E[f(x) \leq -\alpha], \alpha \in \mathbb{R}.\]

At times a function may be proved to be measurable by representing it as the sum of two measurable functions. To prove that the sum of two measurable functions is measurable the following theorem may be used.

**Theorem 22.** If \(f_1\) and \(f_2\) are measurable, then

\[E[f_1(x) > f_2(x)]\]

is also measurable \([4, 69]\).
Theorem 23. If \( f_1 \) and \( f_2 \) are measurable, then \( f_1 + f_2 \) and \( f_1 - f_2 \) are also measurable \([4, 69]\).

Proof. Since \( f_1 - f_2 = f_1 + (-f_2) \), end \(-f_2\) is measurable by Theorem 20, the proof is required only for \( f_1 + f_2 \). Since

\[
E [ f_1(x) + f_2(x) > \varsigma ] = E [ f_1(x) > \varsigma - f_2(x) ]
\]

end \( \varsigma - f_2(x) \) is measurable by Theorem 20, it follows from Theorem 22 that the sets

\[
E [ f_1(x) > \varsigma - f_2(x) ]
\]

are also measurable.

The following theorem expresses another elementary property of measurable functions.

Theorem 24. If \( f(x) \) is measurable, \( f^2(x) \) is also measurable \([4, 69]\).

Proof. Consider the following relationship:

\[
E [ f^2(x) \geq \varsigma ] = E [ f(x) \geq \sqrt{\varsigma} ] \cup E [ f(x) \leq -\sqrt{\varsigma} ], \quad (\varsigma \geq 0).
\]

Then since \( E [ f^2(x) \geq \varsigma ] \) is the union of two measurable sets, \( f^2(x) \) is also measurable.

The following theorem is an immediate consequence of the preceding theorem.

Theorem 25. If \( f(x) \) and \( g(x) \) are measurable real functions, then \( f(x) \cdot g(x) \) is measurable \([2, 185]\).

Proof. The proof follows from the equality

\[
f(x) \cdot g(x) = \frac{1}{4} \left\{ \left[ f(x) + g(x) \right]^2 - \left[ f(x) - g(x) \right]^2 \right\}.
\]
The following theorem concerns functions of a very important class of measurable functions.

**Theorem 26.** Every real-valued function \( f(x) \) continuous in \([a, b]\) is measurable on this closed interval.

**Proof.** Consider the sets

\[
E[f(x) \geq \alpha] = E_\alpha.
\]

These sets are closed and therefore measurable. The fact that each \( E_\alpha \) is closed can be shown as follows: Take a sequence of points

\[
p_v \in E_\alpha, \text{ where } p_v \to p.
\]

Since \( p \in [a, b] \), the function \( f(x) \) is continuous at \( p \), and from \( f(p_v) \geq \alpha \) it follows that

\[
\lim_{v \to \infty} f(p_v) = f(p) \geq \alpha,
\]

which implies \( p \in E_\alpha \).

The following discussion leads to the important conclusion that the limit function of a sequence of measurable functions is measurable. This is helpful since it will be shown that the Lebesgue integral of the limit function of a sequence of integrable functions exists, if the sequence of functions is of bounded variation.

**Theorem 27.** If \( \{f_n(x)\} \) is a sequence of measurable functions, then \( \sup [f_n(x): n = 1, 2, \ldots] \) and \( \inf [f_n(x): n = 1, 2, \ldots] \) are measurable if they exist \([2, 185]\).

**Proof.** Let \( \alpha \) be a real number. Then, if \( f(x) = \sup [f_n(x): n = 1, 2, \ldots] \), then
is measurable, so that \( \sup [f_n(x) : n = 1, 2, \ldots] \) is measurable. Similarly, \( \inf [f_n(x) : n = 1, 2, \ldots] \) is measurable.

**Theorem 28.** If \( \{f_n(x)\} \) is a sequence of measurable functions then \( \lim \sup f_n(x) \) and \( \lim \inf f_n(x) \) are measurable \([2, 185]\).

**Proof.** Let

\[
E \left[ \lim \sup_{n \to \infty} f_n(x) < \varepsilon \right] = \bigcup_{m=1}^{\infty} \bigcup_{n=1}^{\infty} E_{m,n},
\]

where

\[
E_{m,n} = \left[ f_n(x) < \varepsilon - \frac{1}{n} : r = m, m + 1, \ldots \right].
\]

But \( E_{m,n} \) is measurable for every \( m,n \) so that \( \bigcup \bigcup E_{m,n} \) is measurable and \( \lim \sup_{n \to \infty} f_n(x) \) is measurable. Similarly, \( \lim \inf_{n \to \infty} f_n(x) \) is measurable.

The following conclusion is established.

**Corollary 1.** If \( \{f_n(x)\} \) is a convergent sequence of measurable functions and \( f(x) = \lim_{n \to \infty} f_n(x) \), then \( f(x) \) is measurable \([2, 185]\).

**DEFINITION OF THE LEBESGUE INTEGRAL**

The form of the definition of the Riemann integral is not appropriate if the real function \( f(x) \) is "badly" discontinuous since in any contribution to the Riemann sum the value of the
function represents widely varying values of \( f(x) \) over the interval. Lebesgue avoided this difficulty by applying horizontal strips instead of the vertical strips used by Riemann [4, 62]. A definition and discussion of the Lebesgue integral will now be given for which \( f(x) \) is assumed to be bounded and Lebesgue measurable in \([a, b]\).

Let partition \( P = \{y_0, y_1, y_2, \ldots, y_n, y_{n+1}\} \) be given such that

\[ \alpha = y_0 < y_1 < \ldots < y_n < y_{n+1} = \beta \]

where \( \alpha \leq f(x) \leq \beta \). The notation

\[ E_v = \{y_v \leq f(x) < y_{v+1}\} \]

will be used to denote the set of \( x \in [a, b] \) for which \( y_v \leq f(x) < y_{v+1} \) where \( y_v, y_{v+1} \) are elements of \( P \). Form the sums

\[ S_P = \sum_{v=0}^{n} y_v \cdot m(E_v) \quad \text{and} \quad S_P' = \sum_{v=0}^{n} (y_{v+1} - y_v) \cdot m(E_v), \]

where \( S_P \leq S_P' \). Let \( P^* \) be a subdivision or refinement of \( P \), or all the points of \( P \) together with finitely many new ones. It is sufficient to consider a refinement \( P^* \) of \( P \) which contains only one additional point \( \overline{y} \). Let

\[ \overline{y} \in (y_v, y_{v+1}) \]

then

\[ E_v' = E[y_v \leq f(x) < \overline{y}], \quad E_v'' = E[\overline{y} \leq f(x) < y_{v+1}] \]

Hence

\[ E_v = E_v' \cup E_v'' \]

where \( E_v' \) and \( E_v'' \) are disjoint. Therefore

\[ m(E_v) = m(E_v') + m(E_v''); \]
\[ y \cdot m(E) = y \left[ m(E_1') + m(E_2') \right] \leq y \cdot m(E_1') + \bar{y} \cdot m(E_2') \]

and it follows that

\[ s_P \leq s_{P*} \cdot \]

Now consider the sum \( S_P \), a typical term of which is

\[ y_{v+1} \cdot m(E) \]. Then

\[ y_{v+1} \cdot m(E) = y_{v+1} \left[ m(E_1') + m(E_2') \right] \geq \bar{y} \cdot m(E_1') + y_{v+1} \cdot m(E_2')\]

and it follows that

\[ S_P \geq S_{P*}. \]

A combining of the above results yields

\[ s_P \leq s_{P*} \leq S_{P*} \leq S_P. \]

The following theorem can now be proved.

**Theorem 29.** If \( P' \) and \( P'' \) are any two partitions of \([a, b]\), then

\[ s_{P'} \leq s_{P''} \leq s_{P'} \leq S_{P'}, \quad [3, \text{119}]. \]

**Proof.** Form the partition \( P''' = P' \cup P'' \), that is, \( P''' \) is formed by using all the points of \( P' \) together with all the points of \( P'' \). Thus \( P''' \) is a subdivision of \( P' \) and \( P'' \) and

\[ s_{P'} \leq s_{P''} \leq s_{P'''} \leq S_{P'} \]

and

\[ s_{P''} \leq s_{P'''} \leq s_{P''} \leq S_{P'} . \]

From these inequalities it follows that

\[ s_{P'} \leq S_{P''} \leq S_{P''} \leq S_{P'} . \]

It is now possible to form a sequence of subdivisions \( \{P_k\} \).
with norm
\[ d_k = \max (y_{v+1} - y_v), \quad (k = 1, 2, \ldots), \]

such that \( d_k \to 0 \), and such that
\[ s_{p_1} \leq s_{p_2} \leq \ldots \leq s_{p_k} \leq \ldots \leq S_p \leq \ldots \leq s_{p_2} \leq s_{p_1}. \]

Thus \( s_{p_k} \) and \( S_{p_k} \) form bounded monotone sequences whose limits exist and
\[ \lim_{k \to \infty} s_{p_k} = s \leq S = \lim_{k \to \infty} S_{p_k}. \]

Therefore
\[ 0 \leq S - s \leq S_{p_k} - s_{p_k} = \sum_v (y_{v+1} - y_v) \cdot m(E_v) \leq \sum_v d_k \cdot m(E_v) \]
\[ = d_k \sum_v m(E_v) = d_k \cdot (b - a). \]

Since \( d_k \to 0 \) as \( k \to \infty \), \( d_k \cdot (b - a) \to 0 \), and \( S = s \).

The Lebesgue integral can now be defined.

**Definition 8.** The common value \( S = s \) is called the Lebesgue integral of \( f(x) \) in \([a, b]\), denoted
\[ \int_a^b f(x) \, dx, \]
and is equivalent to
\[ \int_a^b f(x) \, dx = \lim_{d_k \to 0} \sum_v y_v \cdot m(E_v) \]
\[ = \lim_{d_k \to 0} \sum_v y_{v+1} \cdot m(E_v), \]
and also
\[ = \lim_{d_k \to 0} \sum_v \lambda_v \cdot m(E_v), \]
where \( \lambda \) satisfies the inequality \( y_v \leq \lambda_v \leq y_{v+1} \) [4, 64].

A function \( f(x) \) for which \( s = S \) in \([a, b]\) is said to be Lebesgue integrable or summable in \([a, b]\).

It will now be proved that the Lebesgue integral, as defined above, is independent of the sequence of subdivisions used, and any sequence of partitions with norms \( d_k \to 0 \) may be employed.

Consider any two sequences of partitions \( \{P_k\}, \{P'_k\} \) with norms \( d_k \) and \( d'_k \to 0 \), respectively. The corresponding sums are \( S_{P_k}, s_{P_k} \) and \( S_{P'_k}, s_{P'_k} \). Form a third partition \( P''_k \) by combining the points of \( P_k \) and \( P'_k \). Thus \( P''_k \) is a subdivision of \( P_k \) and of \( P'_k \); moreover, \( P''_{k+1} \) is a subdivision of \( P''_k \). Let \( s_{P''_k} \) and \( S_{P''_k} \) be the sums corresponding to \( P''_k \) and \( d''_k \to 0 \) be the norm of \( P''_k \).

Also set
\[
S'' = \lim_{d''_k \to 0} s_{P''_k} \quad \text{and} \quad S'' = \lim_{d''_k \to 0} S_{P''_k}.
\]

Then \( s'' = S'' \), and
\[
s_{P_k} \leq s_{P''_k} \leq s'' = S'' \leq S_{P''_k} \leq s_{P'_k},
\]
\[
s_{P'_k} \leq s_{P''_k} \leq s'' = S'' \leq S_{P''_k} \leq s_{P'_k}.
\]

Since \( S_{P_k} - s_{P_k} \leq d_k (b - a) \) and \( S_{P'_k} - s_{P'_k} \leq d'_k (b - a) \), it follows for every \( \varepsilon > 0 \) there exists a \( k_0 \) such that
\[
S_{P_k} - s_{P_k} < \varepsilon \quad \text{and} \quad S_{P'_k} - s_{P'_k} < \varepsilon
\]
whenever \( k \geq k_0 \). It then follows that
\[
S_{P_k} - s'' < \varepsilon, \quad s'' - s_{P_k} < \varepsilon,
\]
\[
S_{P'_k} - s'' < \varepsilon, \quad s'' - s_{P'_k} < \varepsilon, \quad \text{for} \quad k \geq k_0.
\]

Therefore
\[
\lim_{d_k \to 0} s_{P_k} = \lim_{d_k' \to 0} S_{P_k} = \lim_{d_k'' \to 0} s_{P_k'} = \lim_{d_k'''} \pi = S'' = s''.
\]

Thus two completely arbitrary sequences of partitions \( \{P_k\} \) and \( \{P_k'\} \) have the same limit, which implies the integral is independent of the sequence used.

In the definition of the Lebesgue integral the interval \([a, b]\) can be replaced by a measurable set \(M\). Then the \(E_v\)'s are defined as

\[
E_v = \{ x \in M : y_v < f(x) < y_{v+1} \}
\]

and \(m(M)\) replaces \(b - a\). The notation for the integral is

\[
\int_M f(x) \, dx.
\]

With a few additional assumptions the Lebesgue integral can be generalized to include unbounded measurable functions \([4, 66]\). The \(y\)-axis can be subdivided by means of a partition \(P\) such that

\[
\ldots < y_{-v} < \ldots < y_{-2} < y_{-1} < y_0 < y_1 < \ldots < y_v < y_{v+1} < \ldots
\]

with \(y_v \to \infty\) as \(v \to \infty\) and \(y_v \to -\infty\) as \(v \to -\infty\). It must be assumed that the set of differences \((y_{v+1} - y_v)\) is bounded, and the least upper bound of this set the norm \(d\) of \(P\). Now form a sequence of such partitions \(\{P_k\}\) with \(d_k \to 0\). A final assumption must be made, that the infinite sums \(s_{P_k}\) and \(S_{P_k}\) converge. Under these additional assumptions the previous discussion can be modified, and the value \(S = s\) is again the Lebesgue integral. It is helpful to know that, since \(\{s_{P_k}\}\) and \(\{S_{P_k}\}\) are monotone increasing and decreasing sequences, if for any particular value of \(k\), say \(k_0\), the sums \(S_{P_k}\) and \(s_{P_k}\) are
finite, then the corresponding sums are finite for all \( k \geq k_0 \).

**ELEMENTARY PROPERTIES OF THE LEBESGUE INTEGRAL**

To expand the concept of the Lebesgue integral, a few elementary properties are presented. Most of the properties established in this section are for a real function \( f(x) \) which is assumed measurable and bounded on a measurable set \( M \). The exception is the last theorem where \( |f(x)| \) is assumed measurable and bounded.

The following theorem is obtained as a direct result of the limitations placed on \( f(x) \) when defining the Lebesgue integral in the preceding part of this report.

**Theorem 30.** Every function \( f(x) \) which is bounded and measurable in \([a, b]\) is summable in \([a, b]\) \([4, 64]\).

The following elementary property is proved.

**Theorem 31.** If \( f(x) \) is measurable and bounded on \( M \), then \( f(x) \) is summable on each measurable subset \( M_1 \) of \( M \) \([4, 74]\).

**Proof.** Using the definition of a partition previously stated, let \( P \) be a partition such that

\[
\alpha = y_0 < y_1 < \cdots < y_n < y_{n+1} = \beta,
\]

where \( \alpha \leq f(x) \leq \beta \). It can be seen that

\[
\{ x \in M_1 : y_v \leq f(x) < y_{v+1} \} = \{ x \in M : y_v \leq f(x) < y_{v+1} \} \cap M_1 = E_v \cap M_1.
\]

Since \( E_v \cap M_1 \subseteq E_v \),
Therefore the Lebesgue sums involving \( m(E_v \cap M_1) \) converge, since the Lebesgue sums in terms of \( M \) converge.

The following theorem is sometimes called the first law of the mean.

**Theorem 32.** If \( f(x) \) is measurable and bounded on \( M \) (\( \alpha \leq f(x) \leq \beta \) for all \( x \in M \)), then

\[
\alpha \cdot m(M) \leq \int_M f(x) \, dx \leq \beta \cdot m(M) \quad [3, 121].
\]

**Proof.** Let \( \{P_k\} \) be a sequence of partitions with norms \( d_k \to 0 \). It has been shown that

\[
s_{P_1} \leq s_{P_2} \leq \ldots \leq s_{P_k} \leq \ldots \leq \int_M f(x) \, dx \leq \ldots \leq s_{P_k} \leq \ldots \leq s_{P_2} \leq s_{P_1}.
\]

Let \( P_1 \) be the undivided interval \([\alpha, \beta]\). Then \( s_{P_1} = \alpha \cdot m(M) \) and \( s_{P_1} = \beta \cdot m(M) \), and this establishes the theorem.

The following corollaries are both useful and descriptive of the Lebesgue integral.

**Corollary 1.** If \( f(x) > 0 \) on \( M \), \( \int_M f(x) \, dx > 0 \).

**Proof.** This follows from the theorem by letting \( \alpha = 0 \).

**Corollary 2.** If \( m(M) = 0 \), then \( \int_M f(x) \, dx = 0 \).

**Corollary 3.** If \( f(x) = C \), a constant on \( M \), then

\[
\int_M C \, dx = C \cdot m(M).
\]
Proof. This can be seen by letting the interval $[\alpha, \beta] = [C, C + \epsilon]$, where $\epsilon > 0$. In particular, if $C = 1$, then
\[
\int_M C \, dx = \int_M 1 \cdot dx = m(M).
\]

The next theorem asserts the additivity of the Lebesgue integral.

**Theorem 33.** If $f(x)$ is measurable and bounded on $M$ and $M$ is the union of countably many disjoint and measurable sets
\[
M = \bigcup_{k=1}^{\infty} M_k, \quad (M_k \cap M'_{k'} = \emptyset, k \neq k'),
\]
then
\[
\int_M f(x) \, dx = \sum_{k=1}^{\infty} \int_{M_k} f(x) \, dx \quad [3, 121].
\]

Proof. Consider first the simple case in which there are only two disjoint sets:
\[
M = M_1 \cup M_2, \quad (M_1 \cap M_2 = \emptyset).
\]
Since $f(x)$ is bounded, $\alpha \leq f(x) \leq \beta$ on the set $M$. Let $P$ be a partition of the interval $[\alpha, \beta]$ and define the sets
\[
E_v = E[y_v \leq f(x) < y_{v+1}] \quad \text{on } M,
E'_v = E[y_v \leq f(x) < y_{v+1}] \quad \text{on } M_1,
\]
and
\[
E''_v = E[y_v \leq f(x) < y_{v+1}] \quad \text{on } M_2.
\]
Obviously
\[
E_v = E'_v \cup E''_v \quad (E'_v \cap E''_v = \emptyset),
\]
and therefore
\[
\sum_{v=0}^{n} y_v \cdot m(E_v) = \sum_{v=0}^{n} y_v \cdot m(E'_v) + \sum_{v=0}^{n} y_v \cdot m(E''_v).
\]
Let \( \{P_k\} \) be a sequence of partitions with norms \( d_k \). Then as \( d_k \to 0 \),
\[
\int_M f(x) \, dx = \int_{M_1} f(x) \, dx + \int_{M_2} f(x) \, dx.
\]
Therefore the theorem holds for the case of two disjoint sets. Applying the technique of mathematical induction, the theorem can be generalized to the case of an arbitrary finite number "\( n \)". The denumerable case is all that is left to consider. For this case

\[
M = \bigcup_{k=1}^{\infty} M_k.
\]

By the property of measurable sets,
\[
m(M) = \sum_{k=1}^{\infty} m(M_k),
\]
but since this series converges,
\[
\sum_{k=n+1}^{\infty} m(M_k) \to 0 \text{ as } n \to \infty.
\]
Denote
\[
\bigcup_{k=n+1}^{\infty} M_k = R_n.
\]
Since the theorem is already proved for a finite number of component terms, it is possible to write the following equality:
\[
\int_M f(x) \, dx = \sum_{k=1}^{n} \int_{M_k} f(x) \, dx + \int_{R_n} f(x) \, dx.
\]
Then, by Theorem 32,
\[
- \beta \cdot m(R_n) \leq \int_{R_n} f(x) \, dx \leq \beta \cdot m(R_n),
\]
and the measure, \( m(R_n) \), of the set \( R_n \) approaches zero as
n → ∞. It follows that
\[ \int_{R_n} f(x) \, dx \to 0, \]
as \( n \to \infty \), which yields the conclusion.

The following useful property is proved for real functions \( f(x) \) and \( g(x) \).

**Theorem 3.4.** If \( f(x) \) and \( g(x) \) are measurable and bounded on \( M \), then \( f(x) + g(x) \) is summable and
\[ \int_M (f(x) + g(x)) \, dx = \int_M f(x) \, dx + \int_M g(x) \, dx \quad [2, 217]. \]

**Proof.** Let \( \alpha \leq f(x) < \beta \), and \( \delta \leq g(x) < \tau \). Let \( P \) and \( Q \) be partitions of \([\alpha, \beta]\) and \([\delta, \tau]\), respectively, such that
\[ \alpha = y_0 < y_1 < \ldots < y_n < y_{n+1} = \beta, \]
and
\[ \delta = \bar{y}_0 < \bar{y}_1 < \ldots < \bar{y}_N < \bar{y}_{N+1} = \tau. \]

Also set
\[ E_v = E[y_v \leq f(x) < y_{v+1}], \]
\[ \bar{E}_i = E[\bar{y}_i \leq g(x) < \bar{y}_{i+1}] \quad (v = 0, 1, 2, \ldots, n; \]
\[ i = 0, 1, 2, \ldots, N). \]

Define
\[ T_{i,v} = E_v \cap \bar{E}_i \quad (v = 0, 1, 2, \ldots, n; \]
\[ i = 0, 1, 2, \ldots, N). \]

Obviously the set
\[ M = \bigcup_{i,v} T_{i,v} \]
and the sets \( T_{i,v} \) are disjoint, hence
\[ \int_M (f(x) + g(x)) \, dx = \sum_{i,v} \int_{T_{i,v}} (f(x) + g(x)) \, dx. \]

On the set \( T_{i,v} \)
\[ y_v + \bar{y}_i \leq f(x) + g(x) \leq \bar{y}_{i+1} + y_{v+1}, \]
and the first law of the mean implies
\[ (y_v + \bar{y}_i) \cdot m(T_{i,v}) \leq \int_{T_{i,v}} (f(x) + g(x)) \, dx \]
\[ \leq (y_{v+1} + \bar{y}_{i+1}) \cdot m(T_{i,v}). \]

A combination of these inequalities yields
\[ \sum_{i,v} (y_v + \bar{y}_i) \cdot m(T_{i,v}) \leq \int_M (f(x) + g(x)) \, dx \]
\[ \leq \sum_{i,v} (y_{v+1} + y_{i+1}) \cdot m(T_{i,v}). \]

Consider the sum
\[ \sum_{i,v} y_v \cdot m(T_{i,v}), \]
which can be written in the form
\[ \sum_{v=0}^{n-1} y_v \left( \sum_{i=0}^{N-1} m(T_{i,v}) \right), \]
where
\[ \sum_{i=0}^{N-1} m(T_{i,v}) = m \left( \bigcup_{i=0}^{N-1} T_{i,v} \right) = m \left( \bigcup_{i=0}^{N-1} \bar{E}_i \cap E_v \right) = m \left( E_v \cap \bigcup_{i=0}^{N-1} \bar{E}_i \right) = m(E_v \cap M) = m(E_v); \]
so that the original sum may also be written as
\[ \sum_{v=0}^{n-1} y_v \cdot m(E_v). \]

Hence the original sum is the Lebesgue sum \( s_f \) of the function \( f(x) \). Denote this sum \( s_f \). The other sums in the inequality cen
be denoted and evaluated analogously, so that the inequality can be written

\[ s_f + s_g \leq \int_M (f(x) + g(x)) \, dx \leq S_f + S_g. \]

By increasing the number of points of the partitions \( P \) and \( Q \) and by taking the limit in the inequalities above, the theorem is proved.

It is now possible to prove the following elementary property.

**Theorem 35.** If \( f(x) \) is measurable and bounded on \( M \) and \( C \) is a constant, then

\[ \int_M C \cdot f(x) \, dx = C \int_M f(x) \, dx \quad [3, 125]. \]

**Proof.** If \( C = 0 \), the theorem is obvious. Consider the case \( C > 0 \). Since \( f(x) \) is bounded, \( \alpha \leq f(x) < \beta \). Let \( P \) be a partition of the segment \([\alpha, \beta]\) and let

\[ E_v = E[y_v \leq f(x) < y_{v+1}]. \]

It follows that

\[ \int_M C \cdot f(x) \, dx = \sum_{n=0}^{n-1} \int_{M_k} C \cdot f(x) \, dx. \]

On the sets \( E_v \) the inequalities

\[ C \cdot y_v \leq C \cdot f(x) < C \cdot y_{v+1}, \]

hold. Thus by the first law of the mean,

\[ C \cdot y_v \cdot m(E) \leq \int_{M_k} C \cdot f(x) \, dx \leq C \cdot y_{v+1} \cdot m(E_v). \]

Combining these inequalities yields
\[ C \cdot s \leq \int_M C \cdot f(x) \, dx \leq C \cdot S, \]

where \( s \) and \( S \) are the Lebesgue sums for \( f(x) \). The theorem is obtained from this last inequality by taking \( S - s \) arbitrarily small. Finally, consider \( C < 0 \). Here

\[ 0 = \int_M \left[ C \cdot f(x) + (-C) \cdot f(x) \right] \, dx = \int_M C \cdot f(x) \, dx + (-C)\int_M f(x) \, dx, \]

and the proof is completed.

Another useful property of the Lebesgue integral is the fact that equivalent functions have equal integrals. Two functions are said to be equivalent, denoted \( f(x) \sim g(x) \), if \( f(x) = g(x) \) on \( M \) except for a set of measure zero. The property will now be stated as a theorem.

**Theorem 36.** If \( f(x) \) is measurable and bounded on \( M \) and \( f(x) \sim g(x) \) on \( M \), then \( g(x) \) is summable on \( M \) and

\[ \int_M f(x) \, dx = \int_M g(x) \, dx \quad [4, \, 75]. \]

**Proof.** By definition \( f(x) = g(x) \) on \( M - Z \), where \( Z \) is a set of measure zero. Then

\[ \int_M f(x) \, dx = \int_{M-Z} f(x) \, dx + \int_Z f(x) \, dx. \]

Since

\[ \int_Z f(x) \, dx = \int_Z g(x) = 0 \text{ end } \int_{M-Z} f(x) \, dx = \int_{M-Z} g(x) \, dx, \]

it follows that
\[ \int_M f(x) \, dx = \int_{M-Z} g(x) \, dx + \int_Z g(x) \, dx = \int_M g(x) \, dx. \]

An application of this theorem will now be given. Consider the problem of finding the Lebesgue integral of

\[ f(x) = \begin{cases} 
1 & \text{for irrational } x \\
0 & \text{for rational } x, \text{ in the interval } M = [0, 1]. 
\end{cases} \]

Let \( g(x) = 1 \) in \([0, 1]\). Then \( f(x) \sim g(x) \) in \([0, 1]\). By Corollary 3 of Theorem 32

\[ \int_M g(x) \, dx = \int_M 1 \, dx = 1 \cdot (1 - 0) = 1. \]

Hence by the preceding theorem \( f(x) \) is also summable and

\[ \int_M g(x) \, dx = \int_M f(x) \, dx = 1. \]

The following theorem is fundamental to the Lebesgue integral.

**Theorem 37.** If \( f(x) \) is measurable and bounded on \( M \), then \(|f(x)|\) is summable on \( M \) and

\[ \left| \int_M f(x) \, dx \right| \leq \int_M |f(x)| \, dx \quad [4, 76]. \]

**Proof.** Set \( M^+ = M \{ f(x) \geq 0 \} \) and \( M^- = M \{ f(x) < 0 \} \). Then by Theorem 33,

\[ \int_M f(x) \, dx = \int_{M^+} f(x) \, dx + \int_{M^-} f(x) \, dx, \]

and therefore

\[ \int_M f(x) \, dx = \int_{M^+} |f(x)| \, dx - \int_{M^-} |f(x)| \, dx, \]
since \( f(x) = -|f(x)| \) when \( f(x) \) is negative. Since the integrals on the right side of the statement above exist, then the sum of the integrals exists and by Theorem 33 again

\[
\int_{M^+} |f(x)| \, dx + \int_{M^-} |f(x)| \, dx = \int_M |f(x)| \, dx.
\]

This states that \( |f(x)| \) is summable on \( M \). Note that

\[
\int_{M^+} |f(x)| \, dx \geq 0 \quad \text{and} \quad \int_{M^-} |f(x)| \, dx \geq 0.
\]

Then

\[
\left| \int_M f(x) \, dx \right| = \left| \int_{M^+} |f(x)| \, dx - \int_{M^-} |f(x)| \, dx \right|
\]

\[
\leq \int_{M^+} |f(x)| \, dx + \int_{M^-} |f(x)| \, dx
\]

\[
= \int_{M^+} |f(x)| \, dx + \int_{M^-} |f(x)| \, dx = \int_M |f(x)| \, dx,
\]

and the theorem is established.

The converse of the preceding theorem is also proved.

**Theorem 38.** If \( f(x) \) is measurable on \( M \) and \( |f(x)| \) is measurable and bounded, then \( f(x) \) is also summable on \( M \) \([4, 77]\).

**Proof.** If \( f(x) \) is measurable, then the sets \( M^+ \) and \( M^- \) are measurable. Since \( |f(x)| \) is summable,

\[
\int_M |f(x)| \, dx = \int_{M^+} |f(x)| \, dx + \int_{M^-} |f(x)| \, dx.
\]

However, if these two integrals on the right exist,

\[
\int_{M^+} |f(x)| \, dx - \int_{M^-} |f(x)| \, dx
\]
exists and equals $\int_M f(x) \, dx$.

**COMPARISON OF THE Riemann AND Lebesgue INTEGRALS**

For the purpose of comparing the Riemann and Lebesgue integrals, the definition of the upper and lower Riemann integrals, and the definition of the Riemann integral will be assumed to be known to the reader. The Riemann integrals will be denoted by the prefix "R".

The definition of the upper and lower Lebesgue integral is as follows.

**Definition 9.** The upper and lower Lebesgue integrals of the function $f(x)$ defined on a measurable set $M$ are

$$\int_M f(x) \, dx = \inf \{ S_P \}$$

and

$$\int_M f(x) \, dx = \sup \{ s_P \},$$

respectively [2, 205].

The following relationship between the Riemann and Lebesgue integrals will now be given.

**Theorem 39.** If $M$ is a closed interval, then for every bounded function $f(x)$ the following inequalities hold:

$$\int_M f(x) \, dx \geq \int_M f(x) \, dx \geq \int_M f(x) \, dx \geq \int_M f(x) \, dx \geq \int_M f(x) \, dx [2, 206].$$

As a result of this theorem it can be seen that if the
Riemann integral exists, the upper end lower Lebesgue integrals are equal to each other end to the Riemann integral. Hence the Lebesgue integrel exists whenever the Riemenn integrel exists, end has the seme value. The converse of this preceding statement is not true, es may be seen by considering agein the pre-

vious exemple, known es the Dirichlet function. Let

\[
f(x) = 0 \text{ for } x \text{ irrational} \\
f(x) = 1 \text{ for } x \text{ rational in } [0, 1].
\]

Since \( f(x) \) is a constant function of the set \( \mathbb{R}^* \) of rationals end \( m(\mathbb{R}^*) = 0 \), the Lebesgue integrel \( \int_M f(x) \, dx = 0 \), where \( M = [0, 1] \).

For the upper end lower Riemenn integrals of \( f(x) \),

\[
\int_0^1 f(x) \, dx = 1 \text{ and } \int_0^1 f(x) \, dx = 0,
\]

so that the Riemenn integrel of \( f(x) \) does not exist.

Therefore the existence of the Lebesgue integrel does not imply the existence of the Riemenn integrel. Thus the Lebesgue integrel is more general then the Riemenn integrel, et leest for bounded functions.

The Lebesgue integrel is superior to the Riemenn integrel in the eree of finding limits relative to integration processes. Let \( \{f_n(x)\} \) be a sequence of summeble functions on \( M \) which con-

verge to \( f(x) \). Does

\[
\int_M f(x) \, dx = \lim_{n \to \infty} \int_M f_n(x) \, dx?
\]

To see that the preceding equality does not hold necessarily, consider the following exemple: Let \( M = [0, 1] \) end
\[ f_n(x) = \begin{cases} 
 0 & \text{outside } (0, \frac{1}{n}) \\
 n & \text{for } x = \frac{1}{2n} \\
 \text{linear in } \left[0, \frac{1}{2n}\right] \text{ and } \left[\frac{1}{2n}, \frac{1}{n}\right] 
\end{cases} 
\]

Then \( f(x) = \lim_{n \to \infty} f_n(x) = 0 \) since \( f_n(x) = 0 \) for \( x \leq 0 \), and, for each \( x > 0 \), \( n \) can be taken so large that \( \frac{1}{n} < x \), and hence \( f_n(x) = 0 \). Thus \( \int_M f(x) \, dx = 0 \), but \( \int_M f_n(x) \, dx = \frac{1}{2} - \frac{1}{n} \). Therefore it can be seen that without additional conditions the limit and integration processes cannot be interchanged.

A general condition under which the limit and integration processes may be interchanged for Lebesgue integration is known as the uniform boundedness of a sequence.

**Definition 10.** A sequence \( \{f_n(x)\} \) is called **uniformly bounded** on \( M \) if \( |f_n(x)| \leq C \), \( n = 1, 2, \ldots \), where \( C \) is a constant independent of \( n \) and of \( x \in M \) \( [2, 103] \).

The bounded convergence theorem for the Lebesgue integral may now be given.

**Theorem 10.** If the sequence of summable functions \( \{f_n(x)\} \) converges to \( f(x) \) and is uniformly bounded on \( M \), then \( f(x) \) is also summable on \( M \).
\[
\int_M f(x) \, dx = \lim_{n \to \infty} \int_M f_n(x) \, dx \quad [4, 82].
\]

Proof. The function \( f(x) \), as the limit of a convergent sequence of measurable functions, is a measurable function. All functions involved are bounded and measurable, hence they are summable. Since the sequence \( \{f_n(x)\} \) is uniformly bounded on \( M \), there is a \( C > 0 \) such that for every \( n \) and every \( x \in M \),
\[
|f_n(x)| \leq C.
\]
Also, for every \( x \in M \), \( |f(x)| \leq C \). Let \( \varepsilon > 0 \) be given. By the Theorem of Egoroff \([2, 187]\), there is a measurable set \( T \subset M \) such that
\[
m(M - T) < \frac{\varepsilon}{4C},
\]
and \( \{f_n(x)\} \) converges uniformly on \( T \) to \( f(x) \) \([2, 223]\). There is a number \( N \) such that for every \( n > N \) and every \( x \in T \),
\[
|f(x) - f_n(x)| < \frac{\varepsilon}{2 \cdot m(T)}.
\]
Hence for every \( n > N \),
\[
\left| \int_M f(x) \, dx - \int_M f_n(x) \, dx \right| = \left| \int_T f(x) \, dx + \int_{M-T} f(x) \, dx \right.
\]
\[
- \int_T f_n(x) \, dx - \int_{M-T} f_n(x) \, dx \right| \leq \left| \int_T (f(x) \, dx - f_n(x)) \, dx \right|
\]
\[
+ \left| \int_{M-T} (f(x) - f_n(x)) \, dx \right| < \frac{\varepsilon}{2 \cdot m(T)} \cdot m(T) + \frac{\varepsilon}{4C} \cdot 2C = \varepsilon.
\]
Hence for every \( n > N \),
\[
\left| \int_M f(x) \, dx - \int_M f_n(x) \, dx \right| < \varepsilon,
\]
and the theorem is proved.
This theorem is not true for Riemann integrals, for in general the limit function \( f(x) \) is not Riemann integrable under these conditions, as may be seen by the following example.

Assume the rational numbers in \([0, 1]\) to be ordered in a sequence \( r_1, r_2, \ldots, r_m, \ldots \), and set

\[
  f_n(x) = \begin{cases} 
    0 & \text{for } x = r_1, r_2, \ldots, r_m \\
    1 & \text{otherwise}
  \end{cases} \quad \text{in } [0, 1].
\]

Thus the \( f_n(x) \) are Riemann integrable. However,

\[
  \lim_{n \to \infty} f_n(x) = f(x) = 0 \text{ for rational } x \\
  = 1 \text{ otherwise} \quad \text{in } [0, 1],
\]

and \( f(x) \) is not Riemann integrable \([2, 210]\).

A further generalization of Theorem 40 is possible for the Lebesgue integral. This theorem is known as the "dominated convergence theorem".

**Theorem 41.** If the sequence of summable functions \( \{f_n(x)\} \) converges to \( f(x) \) and if

\[
  |f_n(x)| \leq F(x) \quad (n = 1, 2, \ldots)
\]

on \( M \), where \( F(x) \) is summable on \( M \), then \( f(x) \) is also summable on \( M \) and

\[
  \int_M f(x) \, dx = \lim_{n \to \infty} \int_M f_n(x) \, dx \quad [4, 83].
\]

Another area in which the Lebesgue integral is superior to the Riemann integral is in the relation between integration and differentiation. Consider a function \( f(x) \) which is continuous in \([a, b]\) and define
F(x) = \int_{a}^{x} f(t) \, dt \text{ with } x \in [a, b].

F(x) is a primitive or antiderivative of f(x), for either the Lebesgue or Riemann integrals, since the following theorem is true in both cases.

**Theorem 4.2.** If f(x) is continuous on \( x_0 \in (a, b) \), then \( F'(x_0) \) exists and equals \( f(x_0) \) [4, 86].

If the function \( f(x) \) is required to be a bounded derivative, then the Riemann integral does not necessarily yield the primitive, while the following theorem can be proved for the Lebesgue integral.

**Theorem 4.3.** Every bounded derivative in \( [e, b] \) is summable and the Lebesgue integral yields the primitive (antiderivative) up to an additive constant. That is, if \( F'(x) \) is bounded in \( [e, b] \), then for every \( x \in [e, b] \)

\[
\int_{e}^{x} F'(t) \, dt = F(x) - F(e) \quad [4, 87].
\]

**Proof.** Since \( F'(x) \) is measurable and bounded in \( [e, b] \), it is summable in \( [e, b] \). There is a theorem of Dini which states that if \( F'(x) \) is bounded in \( [e, b] \), then

\[
\frac{F(x + h) - F(x)}{h}, \quad (h > 0),
\]

has the same bounds as \( F'(x) \) [4, 87]. Thus using a null sequence \( \{h_n\} \), it follows by Theorem 4.0 that
\[ \int_a^x F'(t) \, dt = \int_a^x \lim_{h_v \to 0} \frac{F(t + h_v) - F(t)}{h_v} \, dt = \lim_{h_v \to 0} \int_a^x \frac{F(t + h_v) - F(t)}{h_v} \, dt = \lim_{h_v \to 0} \left[ \frac{1}{h_v} \left( \int_a^{x+h_v} F(t) \, dt - \int_a^x F(t) \, dt \right) \right]. \]

Set \( t + h_v = \tau \) in the first integral of the last expression. Then

\[ \int_a^x F'(t) \, dt = \lim_{h_v \to 0} \left[ \frac{1}{h_v} \left( \int_a^{x+h_v} F(\tau) \, d\tau - \int_a^x F(t) \, dt \right) \right]. \]

Since \( F(x) \) is continuous in \([a, b]\), then its primitive \( \Phi(x) \) exists there, that is, \( \Phi'(x) = F(x) \), and hence

\[ \int_a^x F'(t) \, dt = \lim_{h_v \to 0} \left[ \frac{\Phi(x + h_v) - \Phi(x)}{h_v} - \frac{\Phi(a + h_v) - \Phi(a)}{h_v} \right] = \Phi'(x) - \Phi'(a) = F(x) - F(a). \]

To show that the preceding theorem does not hold true for Riemann integration, the following example is given.

Let \( s(x) \) be the so-called signum function defined as follows:

\[
s(x) = \begin{cases} 
1 & \text{if } x > 0 \\
-1 & \text{if } x < 0 \\
0 & \text{if } x = 0.
\end{cases}
\]

Let \( M = [-1, 1] \), then \( s(x) \) is bounded in \( M \), but the primitive does not exist \([1, 1/2]\).
WEAKNESSES OF THE LEBESGUE INTEGRAL

A weakness in the Lebesgue integral for a bounded function $f(x)$ occurs as a result of Theorem 37, which states that the integral of $|f(x)|$ also exists whenever $f(x)$ is summable. However, from elementary calculus there are improper integrals for which this property does not hold. For example,

$$
\int_{0}^{\infty} \frac{\sin x}{x} \, dx = \frac{\pi}{2}, \text{ but } \int_{0}^{\infty} \frac{|\sin x|}{x} \, dx
$$

does not exist.

For bounded derivatives the Lebesgue integral is satisfactory, as was stated in Theorem 43; however, unbounded derivatives $F'(x)$ are not necessarily summable. The following is an example of an unbounded derivative which is not summable \cite{4, 89}. Let

$$
F(x) = x^2 \sin \frac{1}{x^2} \text{ for } x \neq 0
$$

$$
= 0 \text{ for } x = 0.
$$

Then

$$
F'(x) = 2x \sin \frac{1}{x^2} - \frac{2}{x} \cos \frac{1}{x^2} \text{ for } x \neq 0
$$

$$
= 0 \text{ for } x = 0,
$$

since

$$
F'(0) = \lim_{h \to 0} \frac{h^2 \sin \frac{1}{h^2}}{h} = \lim_{h \to 0} \frac{h \sin \frac{1}{h^2}}{h^2} = 0.
$$

Now consider the integration of $F'(x)$ between 0 and
This first term of $P'(x)$ is continuous in $[0,a]$; however,

$$
\int_0^a \frac{2}{x} \cos \frac{1}{x^2} \, dx
$$

does not exist. To show this, assume the integral did exist, then by Theorem 37

$$
\int_0^a \frac{2}{x} \left| \cos \frac{1}{x^2} \right| \, dx
$$

also exist. It can be proven that this integral is continuous for every $x \in (0,a)$, $[4, 86]$; hence

$$
\int_0^a \frac{2}{x} \left| \cos \frac{1}{x^2} \right| \, dx = \lim_{\varepsilon \to 0^+} \int_\varepsilon^a \frac{2}{x} \left| \cos \frac{1}{x^2} \right| \, dx .
$$

The zeros of the integrand in (1) are at $x = \sqrt{\frac{2}{(2n+1)\pi}}$ ($n = 0, 1, \ldots$), thus the right member of (2) may be written as

$$
\sum_{n=0}^{\infty} \frac{\sqrt{2/(2n+1)\pi}}{\sqrt{2/(2n+3)\pi}} \frac{2}{x} \left| \cos \frac{1}{x^2} \right| \, dx .
$$

Making the change of variables $\frac{1}{x^2} = z$ in (3), yields

$$
\sum_{n=0}^{\infty} \int_{(2n+1)\pi/2}^{(2n+3)\pi/2} \frac{\cos z}{z} \, dz > \sum_{n=0}^{\infty} \int_{(4n+3)\pi/4}^{(4n+5)\pi/4} \frac{\cos z}{z} \, dz .
$$

This last sum is greater than
\[
\sum_{n=0}^{\infty} \frac{1}{2} \cdot \frac{1}{(4n+5)\pi/4} \cdot \frac{\pi}{2} = \sqrt{2} \sum_{n=0}^{\infty} \frac{1}{4n+5} > \frac{\sqrt{2}}{5} \sum_{n=0}^{\infty} \frac{1}{n+1}.
\]

This last series diverges, hence (1) is infinite. Since (1) does not exist,
\[
\int_0^a \frac{2}{x} \cos \frac{1}{x^2} \, dx
\]
cannot exist, by the contrapositive of Theorem 37.
ACKNOWLEDGMENT

The writer wishes to express sincere appreciation to his major professor, Dr. Robert D. Bechtel, for his time and assistance during the preparation of this report.

ELEMENTARY CONCEPTS CONCERNING THE
LEBESGUE INTEGRAL

by

JOHN R. VANWINKLE

B. A., Harding College, 1961

AN ABSTRACT OF A MASTER'S REPORT

submitted in partial fulfillment of the
requirements for the degree

MASTER OF SCIENCE

Department of Mathematics

KANSAS STATE UNIVERSITY
Manhattan, Kansas

1967
The first part of the report is a discussion of Lebesgue measurable sets, restricted to the real number line. A definition of Lebesgue measure is given in terms of outer and inner Lebesgue measure. After a few elementary properties of Lebesgue measure are established, certain families of sets which are measurable according to the definition are considered. For example, open end closed sets are measurable sets.

The next part of the report is a discussion of Lebesgue measurable functions, the functions "compatible" with Lebesgue measurable sets. A few elementary properties of Lebesgue measurable functions are presented.

In the third part of the report the Lebesgue integral is defined. It is shown that the Lebesgue integral as defined is independent of the sequence of partitions used.

The fourth part of the report is devoted to an elementary discussion of the Lebesgue integral. A few of the properties of the Lebesgue integral are presented, and the Lebesgue integral is compared with the Riemann integral. It is shown that whenever the Riemann integral exists on a closed interval, the Lebesgue integral exists. The converse is shown not to be true by presenting an example. The Lebesgue integral is also shown to be superior to the Riemann integral in the area of finding limits relative to integration processes. The Lebesgue and Riemann integrals are also compared relative to the relation between integration and differentiation. It is shown that the Lebesgue integral of a derivative yields the primitive in an
closed interval for more general conditions than the Riemann integral. The last unit illustrates a weakness of the Lebesgue integral encountered when a derivative to be integrated is not required to be bounded.
