1. OVERVIEW

1.1 Introduction

The purpose of this project is to provide a research tool for musicologists and small music archives in need of cataloging assistance. Development of a tool to assist in this specialized task requires that two areas of musicological research be addressed: incipit matching and document handling.

Typically, musicologists must search through vast quantities of data attempting to gather sufficient information to reconstruct the scope of a collection of music, to ascertain the creative output of a particular composer or group of composers, or to seek all of a single compositional type dating from a specific period. For example, dissertations have been written which survey vocal compositions based exclusively on the "Salve regina" text dating between 1410 and 1550. Similarly, music archives routinely allocate years of staff time in an effort to determine the interconnections between manuscripts belonging to a collection of music developed during a fifty-year span, attempting to link written

documents with musical manuscripts and correctly identify the actual composers of the compositions within the collection. Much of the success of a musicological project is dependent upon the talent of the researchers who sort through this frequently incomplete and often misleading collection of data and, by virtue of their expertise in the area and their knowledge of peripheral data, ultimately reconstruct the most likely solution to the puzzle.

Music historians must deal with a variety of documents in order to complete a given project. Generally, these include letters, music manuscripts, published music, unpublished textual manuscripts, and books. While many documents can be referenced by conventional methods used by researchers in other disciplines, music manuscripts and pre-1900 printed music create problems in the area of erroneous ascriptions and rhythmic, melodic, or key variances introduced by different copyists or publishers. These discrepancies, along with the simple need to derive all known sources of a composition, provide the impetus for the primary thrust of this project -- incipit matching.

In addition to the benefits to be gained from an expert system capable of incipit matching, the process of musicological research can also derive obvious benefits from a database system. The database structure would provide storage and manipulation of data relating to a single project while also assisting in the analysis of this data via the incorporation of rules and inference provided by historical musicologists.

This paper seeks to document a project whose objective is to provide a research tool which will suffice for a variety of musicological projects. The primary emphasis of the system is to store the knowledge of a professional musicological expert in a high-level representation and then to use this information to assist, via incipit matching, in the attribution of compositions to probable composers.

The literature review which follows this section addresses expert systems, the relation of expert systems to musicological studies, and the role of database systems in this arena. The report then continues by describing the development of the musicological tool. Chapter 2 discusses the process of musicological research, describing a typical research project. Chapter

3 presents the requirements of the system being offered as a research tool. This is followed by a description of the design of the system in Chapter 4. Chapter 5 documents implementation and testing of the software. The report concludes with a presentation of conclusions and suggested future enhancements in Chapter 6.

1.2 Literary Review

Resources germane to this project fall into three general categories: (1) database design; (2) artificial intelligence and its application in expert systems; and (3) the integration of expert systems into the field of musicological research. Of these, both expert systems and the use of expert systems as a musicological research tool are relatively new areas of study: indeed, little or no work exists which harnesses the power of an expert system for the benefit of musicology. Database design, on the other hand, is a topic amply covered in computer science circles.

1.2.1 Database Design

A database system is described as a computerized record-keeping system -- that is, a system whose overall purpose is to maintain information and to make that information

available on demand. The sheer volume of data which must be stored, retrieved, manipulated, and referenced as part of any musicological research project makes such a structure essential to the success of the musicological research tool. C. J. Date, in his discussion of why one would choose to employ a database system, summarizes the usefulness of a database system over paper-based methods of record-keeping. He lists (1) compactness, (2) speed, (3) less drudgery, and (4) currency as the most obvious advantages [Da87]. Clearly, the attribute of compactness is welcome relief to the musicological researcher who not only must deal with vast quantities of data, but also must generate equally large quantities of intermediate-level data. The ability to store findings in an easily-retrievable, non-paper form would greatly reduce the workload of musicologists. The attributes of speed, less drudgery, and currency are equally desirable to the music historian whose task neccessitates sifting through an untold numbers of documents in the course of even the smallest research project.

Organization of data within most database systems developed within recent years has been based on relational models. The distinguishing features of relational databases are: (1) the data is perceived by

the user as tables and (2) the operators at the user's disposal for data retrieval or manipulation are operators which generate new tables from old [Da87]. Such a relational model is an ideal storage method for the project currently being described: the whole intent of the system is to create new tables of probable matches or close approximations of incipits based on the use of AI technology.

1.2.2 Expert Systems

In some ways, expert systems seem to be especially suited to musicological research. Certainly, if one accepts Christopher F. Chabris's description of the essential characteristic of an expert system, this is true. Chabris states that expert systems are intended to solve problems in difficult, unstructured domains where knowledge and judgement rather than procedure guides the expert's reasoning [Ch87]. As noted earlier, historical musicology may be among the most unstructured domains since it is, in fact, an interdisciplinary field which requires in-depth knowledge in several areas of study and where many of a scholar's decisions are based on educated intuition rather than simple procedure.

Even clearer justification of the application of expert systems in the field of musicology comes with an examination of Richard Forsyth's description of what makes a suitable candidate for an expert system. [Fo86] states:

> To decide whether a proposed application is likely to benefit from the knowledge-based approach to systems design, you should consider the following questions: (1) Is the problem diagnostic? (2) Is there no established theory? (3) Are the human experts rare? (4) Is the data "noisy" or uncertain.

Again, the field of musicological research can provide resoundingly positive responses to each of these questions.

The design intent of expert systems is to assist users with domain-specific problem-solving expertise by encoding the same problem-solving heuristics that are used by the human experts. Previously-developed successful systems have been employed in a wide spectrum of problem areas including chemical spectrogram analysis (Buchanan & Fergenenbaum, 1978), medical diagnosis (Shortliffe, et al., 1979), mineral exploration (Duda, et al., 1979), genetic engineering (Steefile, 1980), and computer systems configuration (McDermott, 1980). Lehner and Barth [Le85] emphasize that it is clear from the

variety and success of these systems that implementing expert systems on microcomputers is a serious option for potential users of AI technology. Additionally, the use of microcomputers guarantees other factors such as low cost, availablility, and transportability: all these features are essential in building a viable musicological research tool as well.

If one accepts the premise that an expert system can serve as a valid musicological research tool, one must address the concept of expert systems in general. Numerous overviews of the topic are available for study. Parker [Pa88] presents a concise overview of expert systems, citing five elements of an expert system:

(1) facts in the form of rules

(2) an inference engine (procedural knowledge)

(3) an explanation generator

(4) a knowledge acquisition engine

(5) a natural language processor.

Other scholars vary slightly from this format. Forsyth [Fo86] cites four essential components of a fully-fledged expert system:

(1) the knowledge base

(2) the inference engine

(3) the knowledge acquisition module

(4) the explanatory interface.

According to Forsyth, all four modules are critical. A knowledge-based system may lack one of them, but a truly expert system should not. More recently, Vesonder [Ve88] states that rule-based expert systems consist of three components:

(1) a database, more commonly referred to as the working memory

(2) a set of rules, the rule memory

(3) the interpreter, referred to as the inference mechanism.

1.2.3 Musicological Resources

Perhaps due to the "art" involved in musicological research, i.e., the drawing together of knowledge from so many disciplines which must occur in the research process, musicologists have not turned to computers as a true research tool. Robert Skinner, in a review of micro-computer use in music libraries, ascertains that the largest category of music software consists of programs providing computer-assisted instruction. The second largest category of software is that devoted to the

production of actual music: composition, music printing, and musical performance [Sk88].

Clearly, musicologists and music librarians recognize the potential of the computer as a storage medium. In fact, Skinner [Sk88] notes that "CD-Rom and its successors seem natural mediums for encoding composers' complete works so that they can be subjected to various sorts of software-implemented analysis, such as searching for all occurrences of a theme.... Although no music reference works have yet to be published in this format, these may become available in the not-too-distant future, enabling us to search, say, a digital Bach thematic catalog by melodic incipit."
Thus the thought is there, but is yet to be implemented. Instead, the world of music tends to use the computer to assist in teaching music theory or in generating music itself.

While an expert system capable of executing a search and compare mission among musical incipits is yet to be developed, the power of expert systems has been harnessed to invent musical incipits in the style of a particular composer. Ranada [Ra89] describes a newly-completed SUNY/Buffalo PH.D. dissertation by IBM researcher Kemal

Ebciogh, "Report on the CHORAL Project: An Expert System for Harmonizing Four-Part Chorales" which automates the harmonization of chorale melodies in the style of Johann Sebastian Bach. However, even this project deals more with the composition of music than with the historical interpretation of music.

The idea of using computers as a musicological research tool came about in the 1960's and 1970's. Recently, Walter Hewlett and Eleanor Selfridge-Field [He86] initiated a directory listing all known computer-assisted research in musicology in 1986 expressly "...for the purpose of determining what had become of efforts initiated in the 1960's and 1970's to use computers in the field of musicology." They, too, discovered that the use of computers was confined to:

(1) printing music

(2) computer-assisted instruction

(3) cataloging efforts.

Thus the integration of expert systems into the field of musicological research is, for the most part, an unexplored area.

The value of databases as a musicological research tool has been recognized for some time. Yet this, too, is an area besieged by problems. Many scholars point to the lack of standardization and consolidation which limits the usefulness of the research of their colleagues. Both Charnasse [Ch84] and Drummond [Dr84] address the problems encountered by researchers which relate to lack of formalization of database design, structure, and implementation. However, none who attack this problem can offer a clear solution since the use of databases in musicological research may involve diverse music notations, as well as diverse literary and historical references for which no clear-cut standard exists. Warren Hultberg [Hu84], documenting his study of relationships among Spanish music scores of the 16th and 17th centuries, most succinctly summarized both the need and dilemma when he wrote:

> As the study progresses, the pressing need for the development of appropriate data bases becomes increasingly apparent. Generally accepted designations of stylistic features, theory as related to practice, and the basic conventions of the period as seen in the sources, tend to be overly simplified and based on limited material. The development and utilization of data bases designed for the study of the sources considered here, offer possibilities for a greatly enhanced understanding of not only relationships among the Spanish sources, but also their relationships to other literature and repertoires. Quantification of certain aspects of study contributes

to qualitative understanding of the repertoire and its underlying theories.... Appropriate software for comparative studies dealing with analytical problems, practical and theoretical positions, thematic derivation and indexing, is not readily available... for less expensive, micro systems.... Availability of moderately-priced micro systems enhances opportunities for information sharing among scholars in a manner heretofore hardly imaginable, but considerable software development and modification are required if meaningful project advancement is to be achieved.

1.3 Summary

The objective of this project is to produce an online, menu-driven system which will allow research musicologists to build and query a database of information pertinent to their current project. A research tool of this nature has the potential to significantly reduce research time for scholars and students working in musicological research. In an effort to build a more marketable product, implementation of the project is in a format readily available to the personal computer user-community. Ease of use is also a key factor in the development of the product, since the ultimate goal is to decrease the work load of the researcher via improved access to material and computerized decision-making.

2. THE PROCESS OF MUSICOLOGICAL RESEARCH

2.1 Musicology as a Discipline

Musicology, the scholarly study of music, was first introduced as a discipline by Friedrich Chrysander in 1863. Chrysander's intent was to encourage the same high standards of accuracy in the historical study of music as in other areas in the natural sciences and humanities [Ap72]. In the past 125 years, this discipline has become one of sound historical research techniques. Like all historical research, it requires that the professional have a broad knowledge base. A second requirement is that music historians be able to organize and assimilate vast quantities of data, all of which may play some part in the final research product.

Relatively speaking, musicology is a young discipline within the humanities: as such, it is frequently unknown or misunderstood by the masses. For this reason, the following description of typical musicological research projects is provided as a means of establishing the environment of the proposed musicological research tool.

2.2 The Typical Musicologist

Scholars in historical musicology are generally trained in languages, music theory and/or physics, history, and specialized topics in music history. Another area of musicology, that of ethnomusicology, requires additional training in non-Western music theory and culture. Within the arena of historical musicology, researchers frequently specialize in the music of a particular era, i.e., Medieval, Renaissance, Baroque, Classical, Romantic, and Modern, in much the same manner as the art historian. Further specialization will limit the musicologist's area of study to the works of a single composer or group of composers, musical compositions of one genre or style, or compositions from a specific geographic area. Thus, a research project can be devoted to vocal settings of the "Salve regina" text attributed to Franco-Flemish composers between 1425 and 1550. Or a multi-membered research project may deal with the reconstruction of the instrumental repertory of amateur collegii musica functioning in American communities between 1770 and 1830.

2.3 The Research Project

A review of the repertory reconstruction project cited in the previous paragraph provides considerable insight into the musicological research process. It also emphasizes the potential value of a mechanized research tool such as that proposed by this project. Between 1973 and 1982, the National Endowment for the Humanities funded a project which employed four full-time research musicologists, two typists, and supporting staff. All worked toward the reconstruction and documentation of the repertory of the Salem [NC] **Collegium Musicum** and the Bethlehem [PA] Philharmonic Society. Both communities were insular Moravian communities whose strong church ties guaranteed the preservation of a vast archive of letters, diaries, musical compositions, manuscripts, and printed documents which would allow an accurate reconstruction of the musical repertory of these performing groups during America's formative years.

The project was undertaken without computerized assistance, instead using card files and the skill of the researchers to recognize and relocate within those files

any matching incipits, paper watermarks, or references to performances. Since there was no centralized storage medium, problems of conflicting attributions and lack of proper identifications were actually compounded by multiple researchers dealing with a single topic. In short, the project could have been completed much sooner and in a far more thorough manner with the assistance of a mechanized research tool.

2.4 Research Procedures

A typical work day for a researcher assigned to this project included hours spent examining music manuscripts and copying pertinent information on index cards. These abbreviated references included:

1. Call number: a sequential number for subsequent referencing
2. Identification: the composer attribution, composer's dates, title(s)
3. Musical incipit
4. Material quoted from title pages, captions
5. Information about the composition: tempo, key, length
6. Inventory of parts or scoring

7. Miscellaneous comments

8. Cross-references.

Illustration 2.1 shows a page of the final index produced for the catalog of compositions belonging to the relatively small Lititz Congregation Collection [St81].

194 BLÜHER, [AUGUST] (–1839)

Vln III and vla pts identical.

Illustration 2.1

In addition to cataloging, researchers spent hours conversing with colleagues who might have data in the form of other attributions or references which pertained to a special area of interest. Still more time was spent scouring written documents from the era which might contain references to composers, performances, or compositions: such references were, again, meticulously copied on index cards, indexed by date, and cross-referenced by topic.

2.5 Research Product and the Proposed Research Tool

Periodically, an individual researcher would feel confident enough about the data to produce a research paper or article. At that time, the musicologist would search the index file for information which might support a hypothesis evolved during the research process. At this point, as well as the initial information-gathering stage, a musicological research tool could have been of untold assistance. If available, the research tool could identify and locate any duplicate compositions by providing a mechanized search of incipits which would reveal conflicting attributions and multiple copies. A

topical search of written documents could organize literary references and assist in the actual structuring of the researcher's final document. All these are necessary steps in the preparation of an article and all were done without mechanized assistance for the project previously described.

3. REQUIREMENTS

3.1 Introduction

Research musicologists have recognized for quite some time that the computer should be a valuable tool; however, they somehow have failed to develop an integrated approach to the use of this powerful research assistant. Clearly, all who have worked for months amassing data for a research paper, attempting to document and match partially-attributed or incorrectly-attributed compositions or gathering all the necessary literary references for a project, would welcome mechanized relief. Among the many areas within the humanities, musicology perhaps would most benefit from a single, integrated system capable of assisting in the completion of a multi-faceted project.

This system should consist of a user interface capable of providing a straightforward method of accessing the system. As a rule, musicologists are not particularly familiar with automated systems, thus requiring that the proposed system provide a clear set of instructions. In addition to the user interface, the system should include a minimum of four additional features:

(1) an expert system for incipit matching

(2) a graphics capability for entry of these incipits into the system as well as for subsequent displays to the user

(3) a file-handling interface to link the graphics frontend to the database management system

(4) a database management system.

The objective of this project does not include the graphics interface. This will be the design effort of another Kansas State University master's project [Ha89]. Nevertheless, the two designs are closely integrated into a complete system as shown by Illustration 3.1.

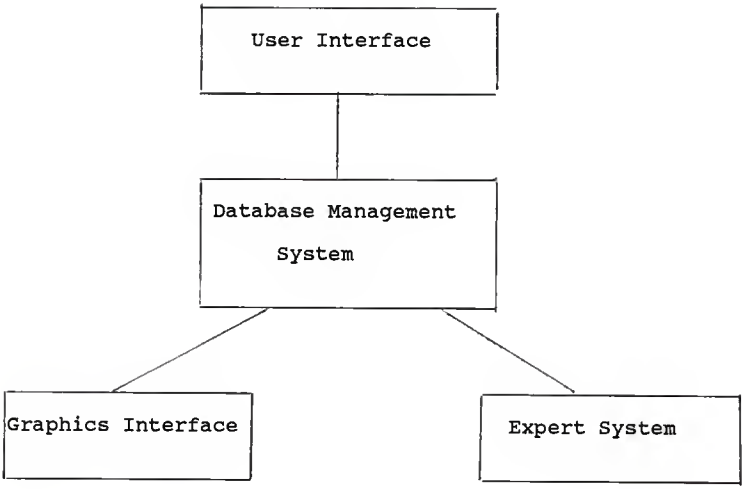

Illustration 3.1

A description of each of these elements, as well as general requirements of the research tool follows.

3.2 General Requirements

The general research requirements of the musicological research tool are three-fold. It should be economical.

Musicologists, like other scholars working in the humanities, are not highly-paid despite the fact that their training must be extensive and broad in scope. For reasons of economy and convenience, the system must run on a personal computer. In addition, personal computers are more familiar to the proposed user since they are frequently employed as word processors by this group of scholars.

A second general requirement of the system is that it should employ non-technical (with regard to computers) language in dealing with the user. When developing the system, the design intent is to never lose sight of the user's needs: musicologists, while they deal in logical relations and decisions which utilize deductive reasoning, are not mathematicians. Often, they are not skilled in technical matters.

A third general requirement of the system is that it should provide the user with extensive storage capacities. Large research projects frequently reference hundreds of documents and music manuscripts. It is essential that the musicologist have a method of storing references to information which might be cited in the

final research product. To do this, the user of the system must be able to add, delete, update, or query the information stored.

3.3 Specific Requirements

This section addresses three requirements of the musicological tool: the user interface is addressed in section 3.3.1; the expert system in section 3.3.2; and the database management system in section 3.3.3.

3.3.1 User Interface

The user interface must be capable of providing the user with simple, easy-to-use menus, interpreting the commands entered by the user, and interfacing with the files provided by the graphics portion of the package. It must respond to user queries with appropriate responses, error messages, or additional user options. It must offer a simple, straightforward set of user instructions, requiring a minimal number of responses from the user.

3.3.2 Expert System

The expert system portion of the system must store high-level representations of the rules that professional

musicologists unconsciously use to interprete their materials. This knowledge will be customized for use by an individual researcher or musicological project to contain specific information for a particular research domain.

The musicological knowledge will be stored in a simple rule-based system. This knowledge base and its use as a research tool will be activated whenever an incipit is added to the data store or modified in any way.

While the basic tenets of the expert system are predefined by the research tool, additional rules may be added to the knowledge base in order to allow customization of the system. This feature is essential since the style considerations of the era which the musicological project is investigating may seriously alter the nature of the rules.

Furthermore, the expert system will allow user interaction: that is, the musicologist may contribute to the final decision of the expert system at break points in the decision process. In addition, the expert system will also communicate with the database system which serves as storage for the knowledge base and incipits.

3.3.3 Database Management System

The relational database management portion of the system must provide storage for the knowledge base of the expert system which consists of the complete set of rules constituting the general knowledge of the expert system. It must also store the domain-specific knowledge of the individual user's application.
Activation of the database management system will be initiated via three methods:

(1) a direct request by the user for retrieval, storage, or updating of information
(2) interaction with the graphical interface
(3) interaction with the expert system.

The database portion of the product must also allow the user to query or update information related to the composers and sources. Stored information will include such data as general information related to sources, probable composer, date of composition, location of manuscript or publication, and the musical incipits themselves.

4. DESIGN

4.1 Introduction

The primary issue addressed by the design chapter is that of integrating the expert system and database technology. This effort, combined with the research efforts of another Kansas State University project [Ha89] which addresses the integration of this design with a graphical interface, produces the research musicological tool. The design chapter concentrates on the incorporation of intelligence into the database processing environment so that the musicological data provided by the user can be intelligently and correctly stored in the musicological database. A second objective of this intelligence incorporation is that decision options can be offered to the user which assist in their research process. Section 4.2 provides a general discussion of the research musicological tool and presents the structural elements of the design effort. Section 4.3 addresses the specific design of the expert system. Section 4.4 addresses the design of the database of musicological information: incipits, composer information, manuscript and literary

references which may be utilized by the expert system. Section 4.5 discusses the interaction of the graphics interface with the expert system and the musicological database. This is followed by a brief summary of the system in section 4.6.

4.2 The Research Musicological Tool - An Overview

The purpose of the research musicological tool is to meet the needs of the independent research musicologist and the small music archives. The needs of this group include:

(1) a clear, concise, easy to use interface
(2) a means to store and manipulate textual data relating to composers and compositions
(3) a facility to enter, store, retrieve, and update musical incipits
(4) assistance in analyzing the data related to their project.

The research musicological tool addresses these needs by providing the following components: a menu-driven user interface which provides access to the musicological project database and the expert system; the musicological

database itself; the graphical interface; and the expert system with all its related maintenance facilities.

Section 4.2.1 discusses the basic structure of the tool. The structure of the music database facility is presented in Section 4.2.2. Finally, the structural division of the expert system maintenance subsystem is discussed in Section 4.2.3.

4.2.1 A Structural Overview

The user interface is the primary method whereby the user communicates with the system. It is, in essence, a scheduler for the system. Communication is maintained via simple-to-use menus and sub-menus. The initial menu offers the user access to the musicological database as well as the expert system maintenance facility.

The system is divided into three layers: (1) the high level menus; (2) the music database facility; and (3) the expert system maintenance facility. The first layer is represented in Illustration 4.1 which identifies the three primary menus.

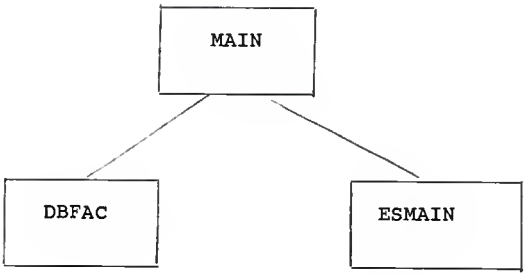

Illustration 4.1

MAIN contains the primary menu. It is the user's first introduction to the system, offering two options: DBFAC, which is the music database facility, and ESMAIN, the expert system maintenance facilities.

DBFAC is a secondary menu which provides the user with add, update, delete, and inquiry functions for the database of musical information.

ESMAIN serves as a secondary menu providing access to the rules employed in the expert system. The user is allowed to add rules, to activate or de-activate rules within the expert system, and to reorganize those rules within the

system as a means of customizing the system to meet the needs of the individual researcher.

4.2.2 DBFAC: The Music Database Facility

The music database facility is scheduled by the user interface whenever a user specifically requests to add, update, delete, or query entries in their file of musicological information. All incipit data is keyed by a system-assigned unique call number for simple retrieval. Source data is keyed by source title. Composer data is keyed by last name, first name, middle initial. Within DBFAC, both the graphics portion of the project and the expert system are key factors. If the intent of the user is to alter only textual data, neither the expert system utility nor the graphics portion of the project is invoked. Textual updates are the sole domain of the database facility. If, however, the user wishes to add, insert, update, or query an incipit, the graphics portion of the system is invoked in order to interface with the user. The add and update functions require that the expert system utility also be invoked as a means of checking for duplicate musical incipits. Thus, a researcher's direct request for a database function could

involve the graphics segment of the system, the expert system segment of the system, and the actual database facility as well.

The music database facility function includes four subdivisions: DBDEL, a delete function; DBADD, which provides an add function; DBUPD, an update function; and DBQUERY, the inquiry function. This relationship is shown in Illustration 4.2.

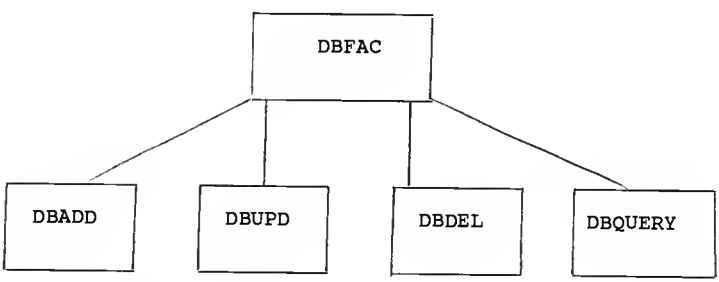

Illustration 4.2

4.2.2.1 DBADD

DBADD is a sub-menu which provides access to three separate functions: ADDINC allows the user to add an

incipit and its associated source and composer information; ADDCOMP allows the addition of an individual composer; and ADDSRC provides for the separate addition of information relating to sources. Illustration 4.3 represents this substructure.

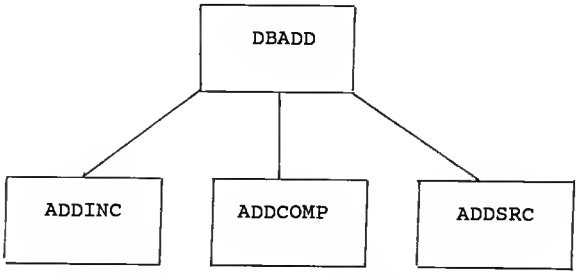

Illustration 4.3

Within this group, ADDINC is the heart of the system. The researcher's request to add an incipit schedules ADDINC. This function then schedules the graphics interface to allow entry of an incipit. Upon scheduling the interface, ADDINC builds an initial file to be used by the interface. This file consists of a function indicator ("A" for add); the proposed next system-

generated call number which will be assigned to the incipit if all expert system checks are sucessfully passed; space for the time signature; key signature; a major-minor indicator; and ten occurrences of associated notes, pitches, and accidentals.

Upon completion of the execution of the graphics interface module, the ADDINC module analyzes the incipit data via INFER, the inference engine. INFER itself schedules six additional modules to assist in the process:

(1) CHGNOTES changes all pitches to a common pattern, converting sharps or flats by adding or subtracting numeric values from the original numeric value of the pitch

(2) RHYTHM looks for rhythmic differences between the proposed incipit and all other incipits in the database, storing the result in a memory variable for later comparisons

(3) NOTES looks for actual pitch differences, storing this data in a memory variable for later comparisons

(4) TIME compares the time signature of the proposed addition to those of other incipits in the

database, storing the result in a memory variable

(5) TRANSP employs CHGNOTES, translating each of the incipits in the music database into a common form prior to examining them for possible transpositions

(6) Finally, RCHECK processes each of the rules stored in the knowledge base, allowing the researcher the ultimate decision concerning whether or not the incipit should be added to the database.

An analysis which produces no other similar incipits in the database allows the researcher to store this incipit. When similar incipits are found, the user is allowed to scroll through these incipits prior to making a decision to add the current incipit. At that point, both source and composer segments may be added to the database via the INCSADD and INCCADD segments. The flow of data through the total ADDINC process is shown in Illustration 4.4.

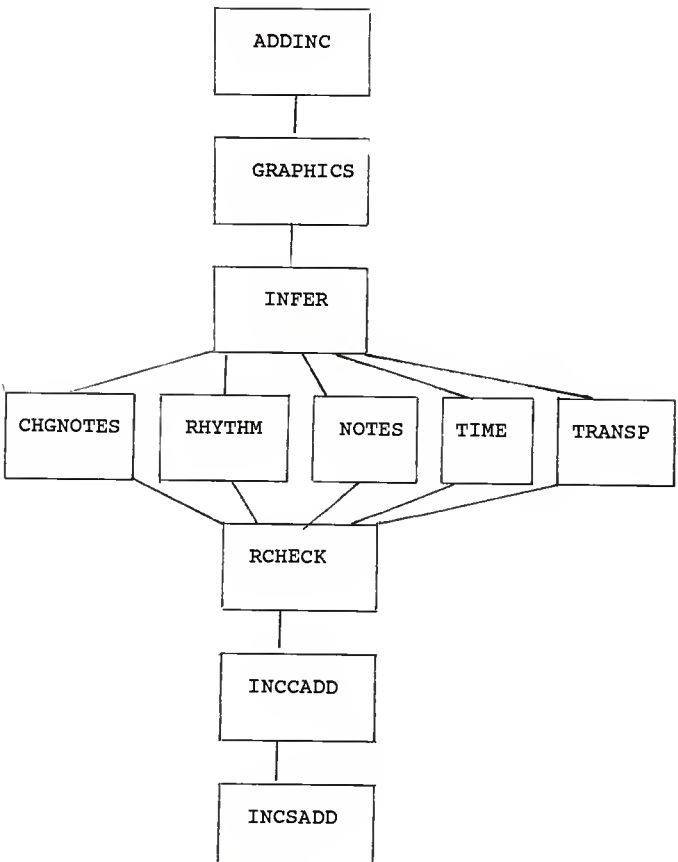

Illustration 4.4

ADDSRC and ADDCOMP add source and composer segments to the music database independent of the ADDINC all-inclusive model.

4.2.2.2 DBUPD

DBUPD, like DBADD, is a sub-menu program. Here the user is offered the opportunity to perform updates of incipit data, source data, or composer data. The structure of the database update function is shown in Illustration 4.5.

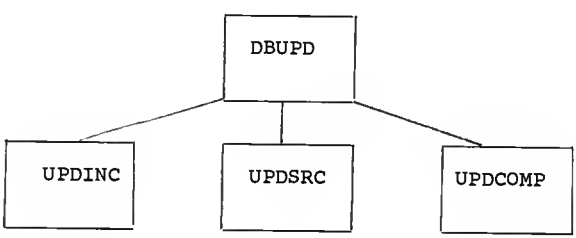

Illustration 4.5

Again, the incipit-processing module UPDINC interfaces with both the graphics program and the inference engine,

screening any changes which might result in a match on an existing incipit within the system.

4.2.2.3 DBDEL

DBDEL is also a sub-menu. All delete processing within the music database is done within this group. Similar in nature to DBUPD, this module allows delete processing for incipits, source records, and composer records. Unlike both ADDINC and UPDINC, DELINC schedules the graphics interface in retrieval mode as opposed to entry mode. During the delete process, the graphics interface allows the researcher to verify the incipit prior to deletion. As seen in Illustration 4.6, DBDEL provides access to the deletion of incipits and their associated sources and composers (DELINC), as well as the separate deletion of source segments (DELSRC) and composer segments (DELCOMP).

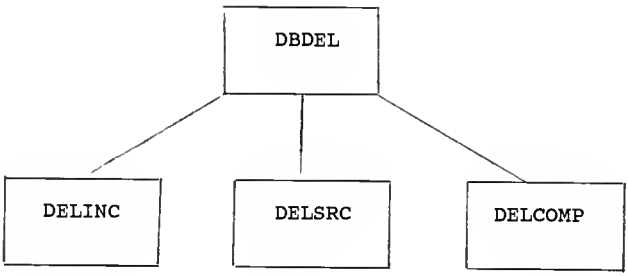

Illustration 4.6

4.2.2.4 DBQUERY

The final function within the music database facility is that of DBQUERY, a module which returns all the sources and composers associated with a given call number within the system.

4.2.3 ESMAIN: Expert System Maintenance

While both the database subsystem and the integrated expert system utility access the graphical interface, the second subsystem, that of expert system maintenance, has no ties to the graphical interface. Nor does it have strong ties to the musical incipit/composer database.

Rather, this subsystem controls its own database of musicological facts and rules. These form the heart of the decision process for the expert system. The basic rules of musicological research are predetermined by the knowledge engineering which must be accomplished prior to the implementation of the project; however, additional rules and fine tuning of the system are at the discretion of the user. In this way, the basic musicological tool can successfully be used by researchers working in a variety of musical eras. Without the ability to alter, add, delete, and restructure the importance of the various rules, the system would be inflexible and, consequently, less useful.

4.2.3.1 ESMAIN Components

Dynamic knowledge engineering must be part of a successful musicological tool: this is the role of ESMAIN, the expert system maintenance portion of the project. ESMAIN is essentially a subsystem which allows the user access to the knowledge base via five methods:

(1) ESADD provides the user with the capability to add rule types to the existing knowledge base

(2) ESRADD allows the addition of individual rules

within these rule types

(3) ESACT allows the user to activate or de-activate the various rule types -- a method of virtual insertion or deletion of the existing rules

(4) ESRACT allows this same activation/de-activation function to be performed on the rules within rule types

(5) ESREORG provides a sub-menu to rule reorganization functions.

This relationship is shown in Illustration 4.7.

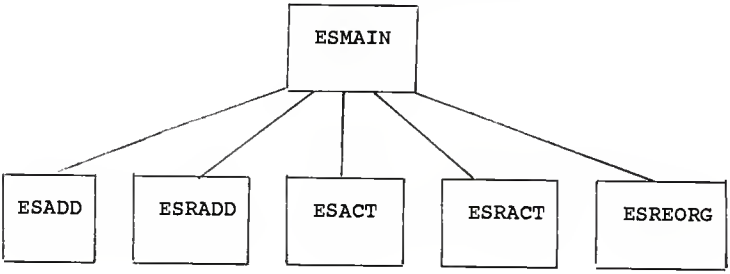

Illustration 4.7

4.2.3.2 ESREORG

ESREORG, represented in Illustration 4.8, is the only sub-menu within this group. It provides access to two

reorganizational features within the expert system: PRERULE1, which allows the researcher to designate the ordering of rule types within the knowledge base, and PRERULE2, which provides this same function for the rules within rule types.

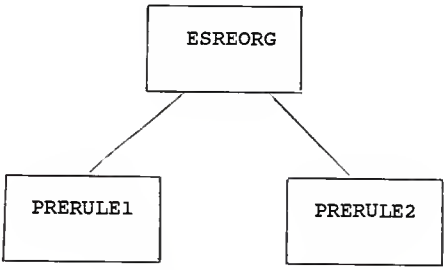

Illustration 4.8

4.3 The Expert System Structure

William R. Arnold and John S. Bowie, in their discussion of artificial intelligence, point out that while AI systems are diverse in their areas of expertise, all have (1) a knowledge base generally made up of rules, (2) an inference engine which performs the tasks that give the system intelligence, and (3) a maintenance engine which

is a program to update the knowledge base or inference engine or both [Ar86]. ESMAIN and its associated functions provide the maintenance engine for the research musicological tool. INFER and its related functions provide the inference engine. The knowledge base itself is provided by a database of rules.

4.3.1 Design of the Knowledge Base

The expert system database stores the knowledge base of musicological rules and musical facts gleaned from a close examination of the process whereby musicologists make intelligent decisions about the materials with which they work. These basic rules and facts may be supplemented by the individual musicologist using the system via the use of the expert system maintenance menus. The database is simple in design, reflecting the method employed by musicologists during the research process. Basically, the database consists of rules organized within rule types, each rule being tagged with the following attributes:

(1) an active-inactive tag which specifies whether the user wishes this rule type to be used in the decision process

(2) a sequence number tag which establishes priorities among the different types of rules

(3) a type indicator tag which indicates the basic category of rule

(4) a second active-inactive tag which allows individual rules within a type to be used

(5) a second sequence number tag which establishes the position of rules within each category

(6) the rule itself.

The combination of rule type, rule type sequence number, and rule sequence number allows each record to be unique. It also allows the researcher to specify that the same general rule be examined multiple times within the decision process, simply by allowing it to exist in multiple type categories. Suppose, for example, that a rule of type NOTES specified the range of note differences allowable between compositions before a match might be identified. This same rule might also exist within the type structure of COPY FAULTS and thus be reconsidered at the time that rule type was scheduled for examination.

Categories of rules might include:

(1) melodic configuration

(2) rhythmic configuration

(3) key considerations

(4) accidentals

(5) manuscript/print data

(6) composer data

(7) probable musical era data.

Obviously, the ideal system should allow new categories to be added by the user to customize the application.

Multiple rules exist in each area, all ordered according to their importance. The user has the option of accepting the standard knowledge base provided by the system. Optionally, the individual user may reorder the rules to suit his own application, insert additional rules, delete rules from the system, or build a new expert based on (1) his own rules, (2) a new ordering of existing rules, or (3) a mixture of existing and new rules. The goal is to provide the musicologist with total flexibility so that the tool can be tailored for each individual application.

4.3.2 Design of the Inference Engine

There are three general designs which typify expert system inference engines: (1) the forward-chaining, or data-driven, method in which a forward-chaining inference engine starts with some information and then tries to find an object that fits the information; (2) the backward-chaining, or object-driven, method whereby a backward-chaining inference engine starts with a hypothesis (an object) and requests information to confirm or deny it; and (3) the rule-value method in which a rule-value inference engine requests as its next piece of information the one which will remove the most uncertainty from the system [Sc87].

Vesonder, discussing rule-based programming in the UNIX system, states that today, most expert systems are built using a rule-based approach [Ve88]. A rule-based methodology, such as that chosen as the basis of the research musicological tool inference engine, is useful for two reasons:

(1) it allows the representation of units of knowledge in the form of rules

(2) because the chunks of knowledge are independent, they can be easily changed without altering the rest of the system.

Vesonder continues his discussion of the rule-based approach by saying that many expert systems have been built using rule-based tools because expertise stated in the form - "If this is the situation, then take this action" - is readily coded into the IF-THEN format of rules.

This format seems especially suited to the design of the research musicological tool. The inference engine designed for this project employs consecutive IF-THEN rule formats, grouping the rules in large chunks of knowledge which may actually be totally bypassed in the logic flow if that is the desire of the user.

4.4 The Database of Musicological Information

The database of musicological information, like that of the expert system rules, is simple in design.
It consists of a incipit segment keyed by a system-generated numeric call number linked to one or more composer segments keyed by composer name. The incipit

segments are also linked to one or more source segments which are uniquely keyed by a source title. An example of the source segment key might be Munich Bayerische Staatsbibliothek 5130. All three segments are linked to one another by the combination of call number, source title and composer name. Illustration 4.9 depicts the entity -relation structure of the musicological information database.

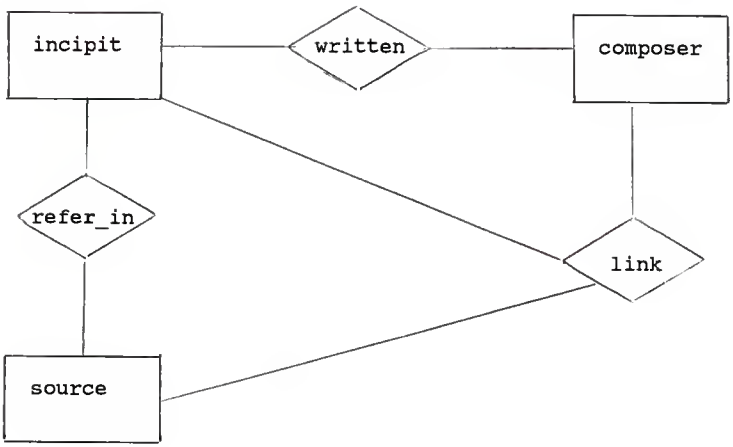

Illustration 4.9

4.5 The Graphical Interface and Expert System

The graphical interface provides the data which feeds the expert system. Whenever multiple similar versions of an incipit exist, the expert system presents these to the researcher via the graphical interface. The graphical interface also allows the user to enter new musical

incipits as part of the musicological database add and update capabilities of the system. The expert system then allows the user to pick and choose which incipits should remain in the working set when break points occur in the expert system logic and user interaction is required. Basically, the graphical interface accepts input from the user and converts this input into a record format which can be transferred to the expert system portion of the design. Once within the realm of the expert system utility, this same data is examined and tested for compliance with the criteria established by the knowledge base database. The graphical interface is never directly called by the user, yet it is an integral part of the total design.

4.6 System Summary

The research musicological tool consists of three primary elements, each of which could become a project in its own right: (1) the expert system; (2) the musical information database; and (3) the graphical interface. Soon after beginning the project, the enormity of the complete system became apparent. For this reason, the system is implemented with a "bare bones" approach. All

facets of the design are addressed; however, the expert system may not possess all the possible rules and rule combinations. Finally, the interaction between the graphical interface and the remainder of the system is addressed in a complete, yet abbreviated fashion. It is the intent of this project to offer the research musicologist a working model of what can be a useful addition to the world of musicological research.

5. IMPLEMENTATION

5.1 Introduction

This chapter addresses the implementation of the research musicological tool. It does not include references to the implementation of the graphical interface segment of the system: the design of this portion of the musicological tool was addressed in detail in another Kansas State University master's project [Ha89]. Those segments of the research musicological tool addressed in this chapter include: (1) the music information database; (2) the expert system with its associated inference engine, maintenance engine, and knowledge base; and (3) the interface between the graphical segment of the project and the database subsystem.

A brief overview of the implementation is given in Section 5.2. Section 5.3 addresses the implementation issues associated with the various databases employed in the research musicological tool. Section 5.4 provides a brief description of the implementation of the expert system itself. Section 5.5 addresses the interface to

the graphical segment of the project. Finally, Section 5.6 discusses the extent of the implementation.

5.2 Implementation Overview

One of the original requirements of the research musicological tool was that the system be implemented on a personal computer. In accordance with this requirement, the project was implemented on a AT&T 6300 personal computer using dBASE III+ Version 1.0. The graphical interface segment of the project [Ha89] used Turbo Pascal Version 5.0. Implementation of the project required two files (an input file and an output file) to pass data between the graphical interface and the database subsystem, a total of eight dBASE files, thirty-five dBASE III+ programs consisting of approximately 1880 lines of code and a Turbo Pascal program [Ha89].

5.3 Database Solutions

Databases were required for three separate parts of the total design effort: (1) the storage of information related to the musical incipits, sources, and composers; (2) the storage of the rules which form the knowledge

base for the expert system; and (3) the intermediate storage of data passed as a file between the graphical interface and the database portion of the project.

The storage of information related to music incipits, sources, and composers required six files. Three of these were used for actual storage of information input by the researcher using the tool. An additional three were used to establish linkage between the data provided by the user. The tool established six separate database work areas with files active in each. Implementation of the research tool did not address null values in the key fields. The files employed for the implementation of the database of musical information are listed in Table 5.1.

TABLE 5.1

MUSICAL INFORMATION DATABASE: STRUCTURES

Database	Field Name	Type	Width

GRAPHF	Callg	call

A study of the tables of database structures reveals one of the problems inherent in dBASE III+: there are no arrays. This, coupled with the 254-characters-per-line restriction imposed by dBASE III+, proved to be a true impediment since it was necessary to pass long lists of note duration and pitch parameters between programs. In addition to the lack of array structures, dBASE III+ has

a restriction regarding the number of files which can be open at one time. Since each program and database structure or index structure is considered to be a file, this was a particular problem. In order to circumvent the files issue, all the programs were placed within one large procedure. Thus, the restriction that only one procedure be active required all parameter passing to occur program to program rather than via the use of additional procedures.

5.4 Expert System Solutions

A large part of any design involving an expert system is knowledge engineering. In order to devise a system which can do the work of the expert, care must be taken to thoroughly understand the steps taken by a musicologist during the research process. Several years experience spent by the author working on a National Endowment for the Humanities research project simplified this process.

One of the more interesting problems associated with the project was that of devising a method whereby the researcher could actually influence the structure of the expert system, dynamically altering the rules within the

knowledge base. Within dBASE III+, a feature exists which allows field names to be used as macros. This instigated the division of the rule itself into three segments: field1, operator, and field2. These were then treated as macros. By limiting the user to selected field names and operators, the system actually provides the user with the capability to set acceptable limits of pitch variations, rhythmic differences, and time signature variations.

5.5 Graphical Interface Solutions

At the outset of the project, the problem of communicating between the database subsystem and the graphical interface seemed insurmountable. However, the ultimate solution was surprisingly simple: it involved employing two files and a temporary dBASE database which was required to match the structure of these two files exactly and the execution of a DOS command within a dBASE program. Whenever an add or update of an incipit is requested by the user, the database subsystem builds a temporary GRAPHF database record with information from the permanent MUSIC database. This database record is used to generate a file. At that point, a DOS command is

issued within a dBASE program to execute the Pascal-based graphical interface. Upon completion of execution, the dBASE program regains control, reading the second file which is generated by the graphical interface and storing it in the temporary GRAPHF database for comparison to existing incipits stored in the MUSIC database.

5.6 Extent

The intent of the implementation was to provide a working tool for the researcher in musicology. In order to do this, all features of the project were implemented with two exceptions:

(1) The TRANSP module within the expert system was not implemented. The logic necessary for this was also used as the basis for the NOTES module. This, implementation of TRANSP was deemed non-essential.

(2) The SCROLL capability within the ADDINC module was not implemented. This feature is useful, but not essential. The design intent of SCROLL was to allow the user to view multiple similar versions of incipits residing on the database prior to choosing to override the expert's decision to not add another similar incipit.

6. Conclusions and Extensions

6.1 Introduction

The motivation of this project was to provide an automated research tool for musicologists and small music archives and to explore the usefulness of expert systems as a potential research tool for music historians.

6.2 Project Conclusions

In the course of completing this project, the following results were achieved:

* Analyzed the problem of providing a research tool for the computer-novice professional musicologist.

* Designed a simple-to_use interactive system employing expert system functions to assist in incipit matching and a database management system to store musicological research information.

* Implemented the research musicological tool for the personal computer using dBASE III+ and a rule-based inference engine.

* Achieved a successful integration of dBASE III+, expert system functions, and a graphical interface to produce a useful tool for scholars in the field of historical musicology.

6.3 Future Enhancements

The research musicological tool can be viewed as a beginning point -- a first step toward mechanized aids for musicologists. In light of that, there are several topics within the scope of the project which would benefit from additional research. The following are recommended areas for further research and development:

* The addition of free form notes to the database subsystem would be particularly beneficial to researchers in any historical discipline.

* The porting of the system to FoxBASE+ or dBASE IV would provide flexibility for the

development of a more functionally-rich product, allowing the features of dBASE without restrictions on array processing and files.

* The design of the current project did not include report capabilities, yet this is an important tool for the research musicologist. Printed lists of incipits and associated composers/sources would be especially helpful during the preparation of articles and papers based on data stored in the research musicological tool.

* A help function which would allow the user to enter an incipit, then view all similar incipits within the system should be implemented to increase the usefulness of the tool.

A MUSICOLOGICAL RESEARCH TOOL: AN EXPERT SYSTEM SOLUTION FOR SMALL PROJECTS

by

JEANNINE STAFFORD INGRAM

B.S., University of North Carolina-Greensboro, 1982

AN ABSTRACT OF A REPORT

submitted in partial fulfillment of the

requirements for the degree

MASTER OF SCIENCE

Department of Computing and Information Sciences

KANSAS STATE UNIVERSITY
Manhattan, Kansas

1989

Abstract

Musicology, the scholarly study of music, was first introduced as a discipline by Friedrich Chrysander in 1863. In the past 125 years, this discipline has become one of sound historical research techniques. It requires that the professional musicologist have a broad knowledge base and be able to organize and assimilate vast quantities of data, all of which may play some part in the final research product. Among the many areas within the humanities, musicology perhaps would most benefit from a single, integrated system capable of assisting in the completion of a multi-faceted project.

The primary motivation of this project was to provide a PC-based automated research tool for musicologists and small music archives and to explore the usefulness of expert systems as a potential research tool for music historians.

The project will establish the need for a research musicological tool, develop an expert system capable of incipit matching and decision processing within the environment of standard musicological research techniques, and develop a database management system suitable for the special needs of small projects in musicology.
