INTRODUCTION

Within the active core volume, the various materials present compete with each other in the absorption of the neutrons present. In reactors that are assumed to be homogeneous, the ratios of the cross sections may be used to well describe the events that occur. However, in a reactor that is considered heterogeneous, which is the usual case, the neutron flux, and hence the rate of absorptions and collisions, may vary greatly between the materials present.

Consider the case where an absorbing rod is separate from the moderating material. If an experimental determination is made of the neutron flux in the moderator and the rod, a depression of the flux within the rod will be evident. This depression, though expected, is greater than that predicted by a diffusion theory calculation using the value of the flux at the surface of the rod as the average flux inside the absorber. This phenomenon is called self-shielding or self-absorption, and it is due to the absorption of a considerable fraction of the incoming neutrons by the nuclei near the surface of the absorbing rod.

Some work has been done which treats self-shielding and capture of neutrons by cylindrical shapes surrounded by a scattering medium (4, 8, 9). Bartels (1) surveyed all the earlier literature (pre-1950) on self-shielding for various absorber geometries. He presented this information in graphical form along with the analytical expressions used
to construct the graphs. In each case, the problem of self-shielding was approached from the viewpoint of a self-absorption factor and an effective cross section. Dwork, et. al. (4) investigated self-shielding for an infinitely long, hollow cylinder. This group rigorously derived equations expressing the self-shielding in a hollow cylinder, and presented their results in graphical form. However, they too used a self-shielding factor and an effective cross section to account for the increased flux depression. Kushneriuk (8) investigated the problem of neutron capture by long cylinders. He arrived at an expression for the self-shielding correction in terms of the average flux in the rod and the unperturbed flux. So, in essence, an effective cross section was determined.

Thus, it appears that the conventional method of treating self-shielding is by determining an effective cross section for the absorber. Then, the proper neutron absorption is obtained by multiplying the average neutron flux inside the absorber by the effective cross section.

A different approach to the problem of self-shielding is one that relates the measured value of the cross section and the physical radius of the rod to an effective rod radius. That is, given a rod of known radius and cross section, an effective rod radius is determined so that the neutron absorption as calculated using the effective rod radius, the neutron flux at the surface of the rod, and the cross section, would match the experimentally determined flux depression.
Thus, to fully utilize the concept of an effective rod radius, one would like to have available graphs that relate the effective rod radius to some dimensionless parameter that is peculiar to the system under consideration. Since the product of the macroscopic absorption cross section and the rod radius is dimensionless, graphs involving this quantity as well as moderator properties would reduce the labor involved in the calculation of the thermal neutron flux level and the power distribution throughout the active core volume.
THEORY

A rigorous solution of the Boltzmann transport equation using spherical harmonics results in an expression for the flux that is an infinite series involving the associated spherical harmonics, i.e., the \( P^m_l (Ω) \) or the associated Legendre polynomials. By considering only a finite number of terms in the series, an approximation to the value of the flux can be made. The accuracy of the approximation depends on the number of terms of the infinite series that are specified. These approximations are symbolically represented as \( P^m_l \) approximations, where the value of \( l \) denotes the order of the approximation; e.g., \( l = 1 \) is a first order approximation, \( l = 2 \) is a second order approximation, and so on. The subscript \( m \) ranges from \(-l\) to \(+l\). A more detailed discussion of the spherical harmonics solution of the Boltzmann transport equation in cylindrical geometry is presented in Appendix A, while a general treatment of this subject can be found in references (3, 5, 7, 11, 16).

The \( P^m_l \) approximation results when the infinite series representation of the flux is terminated after two terms, \( l = 0 \) and \( l = 1 \). The three equations that are obtained lead to a solution for the flux that is identical with the result of ordinary diffusion theory (3, 7, 12, 16) except for the definition of \( D \), the diffusion coefficient. For the \( P^m_l \) approximation, the diffusion coefficient is defined as \( 1/(3\sum_{r} ) \), while for diffusion theory, the diffusion coeffi-
cient is defined as $1/(S\Sigma)$. Keeping in mind this difference in notation, the mathematical methods associated with diffusion theory will be applied to the problem under consideration.

The geometry of this problem is shown in Figure 1. The center region, region I, represents an absorber. The z axis is co-linear with the axis of region I. Region II, which is concentric to region I, represents the moderator. The source is located in the x-y plane, and it can assume any configuration, i.e., point source, plane source, discrete sources, and so forth.

![Figure 1. Coordinate System](image)

As neutrons from the source diffuse in the positive z direction, a depression of the neutron flux in region I, the absorber region, is apparent when the flux is plotted as a function of $r$, the distance from the z axis, on any given z plane. The depression is caused by the excess absorption of neutrons in region I over that of region II. However, the
magnitude of the flux depression due to these absorptions is
greater than would be predicted by diffusion theory.

The increase in the flux depression is the result of
self-absorption within the absorbing media. That is, the
incident neutron flux will be decreased by absorptions at the
surface of the media which decreases the number of neutrons
available for absorption as the neutrons diffuse inward through
the absorber. To obtain the true absorption rate, the flux
could be determined as a function of \( r \), multiplied by the
macroscopic absorption cross section, and the product inte-
grated over the volume of the absorber. This method is cumber-
some and difficult to use (1). A simpler procedure would be
to devise an effective cross section to multiply the flux at
the surface of the absorber to yield the correct neutron absorp-
tion (4). A third method of obtaining the proper neutron
absorption, and the method of this work, is by increasing the
radius of a fictitious absorbing media while allowing the
macroscopic absorption cross section of this media to remain
its measured value.

Thus, for an absorber with a given macroscopic absorption
cross section, an effective absorber radius can be calculated
by varying the radius of the fictitious absorber until the
function that best describes the flux within this absorber
fits the measured values of the flux with the minimum least
squared error. Keeping the above in mind, the mathematical
theory of this problem will now be presented.
Using the subscript "1" for the absorber and the subscript "2" for the moderator, the equations to be satisfied are

\[ \nabla^2 \phi_1 - \kappa_1^2 \phi_1 = 0 \] (1)

and

\[ \nabla^2 \phi_2 - \kappa_2^2 \phi_2 = 0 \] (2)

where

\[ \kappa_1^2 = \Sigma_{a_1} / D_1; \quad \kappa_2^2 = \Sigma_{a_2} / D_2 \] (3)

and

\[ D_1 = 1/(3\Sigma_{r_1}); \quad D_2 = 1/(3\Sigma_{r_2}). \] (4)

In order to obtain a unique solution to Eqs. (1) and (2), boundary conditions must be applied. For this type of problem, the boundary conditions are well known (3, 5, 6, 7, 11, 12) and straightforward. The flux, \( \phi \), must be finite and non-negative throughout the region of diffusion. This condition is clear since the flux can never be infinite or negative. However, it can be zero. At interfaces between media with different diffusion properties, the net neutron current densities and the neutron fluxes are equal. Finally, the neutron flux must go to zero at the extrapolated boundary. The extrapolated boundary is defined as the physical boundary plus 0.71\( \lambda_{tr} \), where, in general, \( \lambda_{tr} \) is small compared to the dimension of the physical boundary.
The following five equations will express mathematically the above boundary conditions:

1. \[ \phi_1(0, z) \neq \infty \] (5)
2. \[ \phi_2(R, z) = 0 \] (6)
3. \[ \phi_1(r, H) = \phi_2(r, H) = 0 \] (7)
4. \[ \phi_1(R_1, z) = \phi_2(R_1, z) \] (8)
5. \[ D_1 \nabla \phi_1(R_1, z) = D_2 \nabla \phi_2(R_1, z). \] (9)

The boundary condition at the x-y plane depends upon the source configuration. For this problem it will be assumed that the source is a plane isotropic source emitting \( S \) neutrons per second per centimeter squared. Thus, the following two boundary conditions are obtained:

6. \[ \frac{S' \phi}{\phi} = \frac{S}{-D_1} \frac{d}{dz} \phi \bigg|_{z=0} = 0 \] (10)

7. \[ \frac{S' \phi}{\phi} = \frac{S}{-D_2} \frac{d}{dz} \phi \bigg|_{z=0} = 0 \] (11)

The Laplacian operator, \( \nabla^2 \), for cylindrical coordinates with no \( \Theta \) dependence is written as

\[ \nabla^2 = \frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} + \frac{\partial^2}{\partial z^2}. \] (12)

Using this, Eq. (1) for region I becomes

\[ \frac{\partial^2 \phi_1}{\partial r^2} + \frac{1}{r} \frac{\partial \phi_1}{\partial r} + \frac{\partial^2 \phi_1}{\partial z^2} - \mu^2 \phi_1 = 0. \] (13)
If the variables are separable, a solution of the form

$$\varphi(r, z) = R(r) Z(z)$$  \hspace{1cm} (14)

is attempted. Utilizing Eq. (14) in Eq. (13) produces

$$\frac{1}{R} R'' + \frac{1}{r R} R' + \frac{1}{Z} Z'' - \lambda_i^2 = 0.$$  \hspace{1cm} (15)

Because the first two terms are functions of $r$ alone, they must be equal to a constant, $\beta^2$. By similar reasoning, the third term is equal to a constant, $\lambda^2$. Thus Eq. (15) becomes

$$\beta^2 + \lambda^2 - \lambda_i^2 = 0$$  \hspace{1cm} (16)

and this equation will be called the separations constants equation.

Now, examining the individual terms of Eq. (15), it is seen that

$$\frac{1}{R} R'' + \frac{1}{r R} R' = \beta^2$$  \hspace{1cm} (17)

and

$$\frac{1}{Z} Z'' = \lambda^2.$$  \hspace{1cm} (18)

A solution of Eq. (17) is

$$R(r) = A I_\nu(\beta r) + B K_\nu(\beta r)$$  \hspace{1cm} (19)

while a solution for Eq. (18) is

$$Z(z) = C \sinh \lambda z + E \cosh \lambda z.$$  \hspace{1cm} (20)
Thus, the complete solution before the application of the boundary conditions is

\[ \phi(r, z) = [AI_0(\beta r) + BK_0(\beta r)][C \sinh \lambda z + EC \cosh \lambda z]. \quad (21) \]

In order that Eq. (5) be satisfied

\[ B = 0. \quad (22) \]

Changing the argument of Eq. (20) from \( \lambda z \) to \( \lambda(H-z) \), which is valid for a slab geometry coordinate, Eq. (7) is satisfied if

\[ E = 0. \quad (23) \]

Thus,

\[ \phi_1(r, z) = AI_0(\beta r) \sinh \lambda(H-z). \quad (24) \]

Applying the same procedures to region II, the solution to Eq. (2) may be written as

\[ \phi_2(r, z) = [FJ_0(\alpha r) + GY_0(\alpha r)][MS \sinh \gamma z + NC \cosh \gamma z] \quad (25) \]

where the separations constants equation for this region is

\[ -\alpha^2 + \gamma^2 - \lambda^2 = 0. \quad (26) \]

The choice of sign on the \( \alpha^i \) term is determined by the type of solution desired in the outer region. Application of Eqs. (6) and (7) to Eq. (25) produces
\[ \phi_2(r, z) = B [J_0(\alpha r) - TY_0(\alpha r)] \text{Sinh } \gamma(H-z) \]  

(27)

where

\[ T = J_0(\alpha R2)/Y_0(\alpha R2). \]  

(28)

Now, an auxiliary function \( U_0(\alpha r) \) is defined (2) as

\[ U_0(\alpha r) \equiv J_0(\alpha r)Y_0(\alpha R2) - Y_0(\alpha r)J_0(\alpha R2). \]  

(29)

Some of the properties of this function are discussed in Appendix C. Using Eq. (29), Eq. (27) becomes

\[ \phi_2(r, z) = B^* U_0(\alpha r) \text{Sinh } \gamma(H-z) \]  

(30)

where

\[ B^* = B/Y_0(\alpha R2). \]

When boundary condition four, Eq. (8), is applied to Eqs. (21; 30), it is seen that

\[ \text{AI}_o(\beta R1) \text{Sinh } \lambda(H-z) = B^* U_0(\alpha R1) \text{Sinh } \gamma(H-z) \]  

(31)

or writing Eq. (31) in a different form

\[ K_1 \text{Sinh } \lambda(H-z) = K_2 \text{Sinh } \gamma(H-z). \]  

(32)

Rearrangement of Eq. (32) gives

\[ K_3 = \frac{\text{Sinh } \lambda(H-z)}{\text{Sinh } \gamma(H-z)}. \]  

(33)

Eq. (33) implies that, regardless of the value of \( z \),
the left-hand side of the equation is always equal to the same constant. In order for this to be true, \( \lambda \) and \( \gamma \) would have to be equal. Thus, Eq. (26) may be written as

\[
- \alpha^2 + \lambda^2 - \gamma^2 = 0.
\] (34)

When boundary conditions four and five, Eqs. (8) and (9), are applied to Eqs. (24) and (30)

\[ A_1 I_1(\beta R_1) = B^* U_0(\alpha R_1) \] (35)

and

\[ D_1 A R_1 I_1(\beta R_1) = -D_2 B^* \alpha U_1(\alpha R_1). \] (36)

Dividing Eq. (36) by (35)

\[ \frac{D_1 \beta I_1(\beta R_1)}{I_0(\beta R_1)} = -\frac{D_2 \alpha U_1(\alpha R_1)}{U_0(\alpha R_1)}. \] (37)

Solving Eq. (37) for \( \beta \) gives

\[ \beta = -\frac{\alpha U_1(\alpha R_1)}{U_0(\alpha R_1)} \cdot \frac{D_2 I_1(\beta R_1)}{D_1 I_1(\beta R_1)}. \] (38)

Examination of Eq. (38) reveals that it is transcendental in nature and requires an iterative type of solution to determine the constants \( \alpha \) and \( \beta \). But in solving for \( \alpha \) and \( \beta \), it must be remembered that they are related by Eqs. (16) and (34); i.e.,

\[ \alpha^2 = \gamma^2 - \lambda^2 - \beta^2. \] (39)
Because of the periodicity of the functions \( J_0(r) \) and \( Y_0(r) \) that compose the function \( U_0(r) \), an infinity of solutions is obtained for Eq. (38). Therefore, Eq. (39) now becomes

\[
\alpha_n^2 = \lambda_1^2 - \lambda_2^2 - \beta_n^2
\]  

(40)

and the expressions for the fluxes are now written as

\[
\Phi_1(r, \gamma) = \sum_{n=0}^{\infty} A_n I_0(\beta_n r) \cosh \lambda_n (H-\gamma)
\]

(41)

and

\[
\Phi_2(r, \gamma) = \sum_{n=0}^{\infty} B_n^* U_0(\alpha_n r) \sinh \lambda_n (H-\gamma).
\]

(42)

The subscript "\( n \)" on \( \lambda \) is because of the infinity of values of \( \alpha \) and \( \beta \).

The application of boundary conditions six and seven, Eqs. (10) and (11), yield

\[
S = D_1 \int_{R_1}^{\infty} \sum_{n=0}^{\infty} A_n \lambda_n I_0(\beta_n r) \cosh \lambda_n H \, dr
\]

(43)

and

\[
S = D_2 \sum_{n=0}^{\infty} B_n^* \lambda_n U_0(\alpha_n r) \cosh \lambda_n H.
\]

(44)

Utilizing the orthogonality relations for Bessel functions, the coefficients for Eq. (43) are obtained in the usual manner. Thus

\[
\sum_{p=0}^{\infty} \int_{R_1}^{\infty} S \cdot J_0(\beta_p r) \, dr = \lambda_n D_1 \sum_{p=0}^{\infty} \int_{R_1}^{\infty} A_n r J_0(\beta_p r) I_0(\beta_n r) \cosh \lambda_n H \, dr
\]

(45)
so that

\[ A_n = \frac{S \int \psi(\beta_nR1)}{D \lambda_n \{I_x(\beta_nR1) + I_z(\beta_nR1)\}} \text{Cosh} \lambda_n H \]  

if \( S \neq S(r) \). Similarly, applying the orthogonality relations for \( U_o(\alpha_n r) \) as developed in Appendix C, the coefficients \( B_n \) can be determined. Thus

\[ \sum_{P=0}^{\infty} \int_{R1}^{R2} S \psi U_o(\alpha_P r) dr = \left\{ D \sum_{P=0}^{\infty} \sum_{n=0}^{\infty} \int_{R1}^{R2} B_n^* \lambda_n r U_o(\alpha_P r) U_o(\alpha_n r) dr \right\} \text{Cosh} \lambda_n H \]  

so that

\[ B_n^* = \frac{S\left\{ \frac{2}{\pi} + R1 \mathcal{K}_1 U_o(\alpha_nR1) \right\}}{D \lambda_n \left\{ \left( \frac{2}{\pi} \right)^2 - (\alpha_n^2 + \mathcal{K}_1^2) \left[ R1 U_o(\alpha_nR1) \right]^2 \right\} \text{Cosh} \lambda_n H} \]  

if \( S \neq S(r) \) and as before

\[ B_n^* = B_n / Y_o(\alpha_nR2) \]  

where

\[ \mathcal{K}_1 = - \frac{\alpha_n U_o'(\alpha_nR1)}{U_o(\alpha_nR1)} \]  

(See Appendix C).  

Another set of source boundary conditions that might be of interest is one where the source is considered to be zero at the \( x-y \) plane in the absorber, while the source in this position in the moderator remains as described by Eq. (11).

To describe the boundary conditions for this new source condition, the partial neutron current equations
are used. That is,

\[ J_+ (y) \bigg|_{y=0} = 0 \quad \text{for } 0 \leq r \leq R_1 \quad (\text{Region I}) \]  

(51)

\[ J_+ (y) \bigg|_{y=0} = S \quad \text{for } R_1 < r \leq R_2 \quad (\text{Region II}) \]  

(52)

where the partial neutron current in the positive direction is defined as (6)

\[ J_+ (y) = \frac{\phi}{4} - \frac{D}{2} \frac{d\phi}{dy}. \]  

(53)

Using Eqs. (41) and (42) as definitions for \( \phi \) and \( \phi \) respectively, the following two equations are obtained:

\[ \sum_{n=0}^{\infty} A_n I_0 (\beta_n r) \sinh \lambda_n H \frac{4}{4} + \frac{D}{2} \sum_{n=0}^{\infty} A_n \lambda_n I_0 (\beta_n r) \cosh \lambda_n H = 0 \]  

(54)

and

\[ \sum_{n=0}^{\infty} B_n^* U_0 (\alpha_n r) \sinh \lambda_n H \frac{4}{4} + \frac{D}{2} \sum_{n=0}^{\infty} B_n^* U_0 (\alpha_n r) \lambda_n \cosh \lambda_n H = S. \]  

(55)

Working first with Eq. (54), it is seen that

\[ \sum_n A_n I_0 (\beta_n r) \left\{ \sinh \lambda_n H + 2D_1 \lambda_n \cosh \lambda_n H \right\} = 0. \]  

(56)

If \( \beta_n \) is real, \( I_0 (\beta_n r) \) is never equal to zero, and a trivial solution is obtained if \( A_n = 0 \). Therefore, the bracketed term must equal zero. After transposing, the bracketed term may be written as
\[ \tanh \lambda_n H = -2D_1 \lambda_n . \] (57)

Since the hyperbolic tangent is always greater than or equal to zero if its argument is positive, the possible solutions to Eq. (57) are

\[ \lambda_n = 0; \quad \lambda_n = i \xi_n . \] (58)

When \( \lambda_n = 0 \), solution of Eq. (18) yields

\[ Z = C_1 + C_2 y . \] (59)

Application of Eq. (7) leads to

\[ Z = C_1 (1 - z/H) = C_3 (H - z) \] (60)

and the flux equation for the absorber is written as

\[ \phi_i = \sum_n A_n I_o(\beta_n R)(H - z). \] (61)

Utilizing the boundary condition at the interface, Eq. (8)

\[ \sum_n A_n I_o(\beta_n R1)(H - z) = \sum_n B_n^* U_o(\alpha_n R1) \sinh \gamma_n (H - z) \] (62)

or

\[ \sum_n A_n I_o(\beta_n R1) \frac{Sinh \gamma_n (H - z)}{H - z} = \sum_n B_n^* U_o(\alpha_n R1) \] (63)

Since the left-hand side is a constant, the above implies that, regardless of the value of \( z \), the
right-hand side is equal to a constant. For this to be true, \( \gamma_n \) must equal zero so that the solution of Eq. (2) will yield the same result as the solution of Eq. (7) when \( \lambda_n \) is equal to zero.

However, from physical consideration of the system, it is known that the attenuation of the flux in the \( z \) direction is exponential and not linear as these results suggest. Thus, one must conclude that the solution \( \lambda_n = 0 \) does not well describe the physical situation and is invalid.

Now consider the case when \( \lambda_n \) is imaginary and let \( \lambda_n = \imath \xi_n \); then Eq. (57) becomes

\[
T \tan \xi_n H = -2D_1 \xi_n. \tag{64}
\]

An examination of a plot of the tangent reveals that an infinity of solutions to Eq. (64) are possible. Because the form of the flux equation with \( \lambda_n = \imath \xi_n \) is

\[
\phi_i = \sum_n A_n I_o (\beta_n R)[\imath \sin \xi_n (H - z)] \tag{65}
\]

negative imaginary values of \( A_n \) are necessary to obtain positive values of \( \phi_i \). Hence, the argument of the sine term must be positive.

Application of the interface boundary condition, Eq. (8), leads to the condition that

\[
\sum_n \frac{A_n I_o (\beta_n R)}{B_n U_o (\alpha_n R)} = \frac{S \sin \xi_n (H - z)}{S \sin \xi_n (H - z)}. \tag{66}
\]
Again, it is evident that the right-hand side is equal to a constant which implies that $\gamma_n$ is imaginary, so that once more $\lambda_n = \gamma_n$.

The sine distribution in the $z$ direction does not contradict the physical situation. Since the model chosen calls for a plane source of monoenergetic neutrons at the source plane, the value of the neutron flux at the source plane should be largest and decrease to zero at the extrapolated height of the system. The sine function as defined fulfills these conditions.

To determine the form of the $A_n$ coefficients, the interface boundary condition, Eq. (8), must be applied, and the $A_n$'s can then be expressed in terms of the $B_n^*$'s. Therefore, the forms of the coefficients $B_n^*$ must be determined. Working with Eq. (55), rearrangement yields, after the substitution of sine and cosine for hyperbolic sine and cosine,

$$4S = \sum_n B_n^* U_o(\alpha_n r) \left[ S \sin \lambda_n H + 2D_2 \lambda_n \cos \lambda_n H \right] \quad (67)$$

where the bracketed term is some constant, $C_n$ say. Applying the orthogonality relation for $U_o(\alpha_n r)$ as developed in Appendix C

$$4S \int_{R_1}^{R_2} r U_o(\alpha_{\gamma n} r) \, dr = \sum_n \int_{R_1}^{R_2} B_n^* r U_o(\alpha_{\gamma n} r) U_o(\alpha_n r) \, C_n \, dr \quad (68)$$

which becomes
Thus, it is seen that the coefficients $B_j^*$ are similar in form to those obtained from Eq. (48). Now Eq. (8) is applied to find $A_n$:

$$\sum_n A_n I_o(\beta_n R1)(\chi \sin \xi_n (H-z)) = \sum_n B_n^* U_o(\alpha_n R1)(\chi \sin \xi_n (H-z))$$

and

$$A_n = \frac{B_n^* U_o(\alpha_n R1)}{I_o(\beta_n R1)}$$

where $B_n^*$ is defined by Eq. (69).

A second approach to formulating this source condition is by use of the net current equation at the source plane; i.e.,

$$J(z)|_{z=0} = 0 \quad 0 \leq r \leq R1$$

$$J(z)|_{z=0} = S \quad R1 < r \leq R2$$

where $J(z)$ is defined (6) as

$$J(z) = - \nabla \phi.$$
and

\[ D_2 \sum_{n} B_n^* U_0(\alpha_n r) \lambda_n \cosh \lambda_n H = S, \quad (75) \]

Examination of Eq. (74) reveals that trivial solutions are obtained if either \( A_n = 0 \) or \( \lambda_n = 0 \). Assuming that \( \beta_n \) is real, \( I_\circ(\beta_n r) \) is never equal to zero. Thus, \( \lambda_n \) must be imaginary for a solution to exist. Letting \( \lambda_n = i \xi_n \), Eq. (74) becomes

\[ D_1 \sum_{n} A_n I_\circ(\beta_n r) (i \xi_n \cos \xi_n H) = 0, \quad (76) \]

The roots of this equation occur at

\[ \xi_n = (2n + 1) \pi / 2 H, \quad (77) \]

By arguments similar to those used to obtain Eq. (66), it can be shown that \( \gamma_n \) must also be imaginary. Thus, Eq. (75) becomes

\[ D_2 \sum_{n} B_n^* U_0(\alpha_n r) (i \xi_n \cos \xi_n H) = S, \quad (78) \]

Applying the orthogonality condition for \( U_0(\alpha r) \) as developed in Appendix C

\[ S \int_{R_1}^{R_2} r U_0(\alpha_j r) dr = \]

\[ D_2 \sum_{n} B_n^* i \xi_n \cos \xi_n H \int_{R_1}^{R_2} r U_0(\alpha_j r) U_0(\alpha_n r) dr \]

which becomes

\[ B_j^* = \frac{\xi_n \cos \xi_n H \left[ \frac{\xi_j^2 + \alpha_j + R_1^2}{2} \right]}{\left[ R_1 U_0(\alpha_j R_1) \right]^2}, \quad (80) \]
Application of the interface boundary condition, Eq. (8), yields an expression for $A_n$. Thus,

$$\sum_n A_n I_o(\beta_n R1)(\alpha_n R1) S_n \xi_n(H-3) =$$

$$\sum_n B_n^* U_o(\alpha_n R1)(\alpha_n R1) S_n \xi_n(H-3)$$

and

$$A_n = \frac{B_n^* U_o(\alpha_n R1)}{I_o(\beta_n R1)}$$

where $B_n^*$ is defined by Eq. (80).

The net current source condition may be a more accurate description of the events that occur at the source plane than the partial current source condition since the net current equation accounts for neutrons that enter into the source region and then reenter the rod-moderator region. The partial current equation considers only those neutrons that are moving in the proper direction and assumes that all events that direct neutrons in the opposite direction are losses. The fact that the net current condition has implied that an imaginary source is necessary definitely will hinder its physical application although it is an interesting mathematical criterion. Therefore, the partial current boundary condition would normally be utilized.

Thus, for the case of a known plane isotropic source of neutrons located in the x-y plane, the value of the effective rod radius can be determined analytically by solving, using a trial and error iterative procedure, Eqs. (38), (40), (46),
and (48). If the value of the source is unknown, the effective rod radius can be determined numerically by fitting an experimentally determined flux plot by a method of least squares while varying the rod radius to reduce the least square error to a minimum. An IBM 1620 computer program that determines the effective rod radius and the unknown coefficients in the flux equations is described in Appendix F.
EXPERIMENTAL PROCEDURE

To determine the effective rod radius, one must first obtain, by a suitable method, an experimental flux plot in the absorber and moderator region. A method of doing this, and the method employed in this work, involved the use of gold wire and gold foil in conjunction with absorber rods of two different diameters utilized with a graphite thermal column of a nuclear reactor.

The absorbing rod used to obtain the data for the flux plot was cut into three sections. Ideally, these sections were of such a length that the end effects due to the length of the sections were negligible, and the center section of the rod was of sufficient length that the z dependence of the flux was eliminated.

Slots were cut into each end of the center section of the rod, and these slots were of sufficient depth and width that they accommodated both the foil and the wire. The wire or foil when in position extended from the edge of the special graphite stringer completely through the absorber rod. With the wire and rod in place in the stringer, it was then placed into the graphite thermal column and the irradiation period was begun.

For the case where two different rod diameters were used, the stringer was constructed so that when the one rod was being used to amass the data, a graphite rod of the same material as the stringer was placed in the groove for the
second rod. The purpose of the graphite rod was to eliminate the void space that would have been present when only one rod was placed in the stringer.

At the conclusion of the period of irradiation, the reactor was shut down, and the special stringer was removed from the thermal column. The stringer was then placed in a guarded area to permit the short lived isotopes of the absorber rod to decay away. After a suitable cooling off period, the wires or foils were removed from the rod-stringer assembly and transported to the counting facility.

To count the wire, a wire counting facility was needed. This facility consisted of a wire guide to measure the position of the wire in relation to the center of the rod and a Geiger counting tube. The counting tube was shielded to prevent the beta radiation from scattering and streaming into the sensitive volume of the tube.

A foil counting facility similar to the one constructed to count the wire was feasible, but a more simple arrangement was employed. The foil was taped to a piece of graph paper and then cut into small strips at appropriate intervals. These strips were then placed on a special plancet that insured reproducible geometry with respect to the counting tube, and the small foils were then counted using a gas flow proportional counter.
ANALYSIS OF DATA

In the theoretical development of the two region $P_1$ transport model, it was shown that an analytic expression for the neutron flux in both regions can be determined for a given absorber radius once a source condition is established. However, to determine the effective rod radius, it was necessary to fit a set of experimental data with the proper expressions for the flux while varying the absorber radius. An IBM 1620 computer program was written for this purpose, and it is described in Appendix F.

The effective rod radius was determined by a trial and error procedure which strived to minimize the sum of the weighted squares of the residuals between the experimental values and the values calculated from the theoretical expressions for the neutron flux in both regions. The weighting function used was that one which required that the residual between the calculated value at any point and the experimental measurement should lie within the statistical standard deviation.

Another point considered in the fitting of the experimental data was the number of harmonics necessary to best fit the data. Provision was made in the computer program to accommodate up to five harmonics. However, the inclusion of more than three harmonics was deemed inadvisable since the accuracy of the data did not warrant a more precise analysis.

All of the data were analyzed using one harmonic, and
two different situations were considered in the analysis. In one case, the value obtained from the solution of the transcendental equation $\lambda/\Sigma = \tanh \lambda/\Sigma_s$ was used for $\lambda$ in the rod; in the second case, the diffusion theory value for $\lambda$ in the rod, $\lambda = (3 \Sigma_a \Sigma_s)^{1/3}$, was employed. The purpose of this approach was to show the difference between asymptotic theory and the $P_1$ transport theory in the absorbing media, since diffusion theory is true only when $\Sigma_a \ll \Sigma_s$.

Three particular sets of data were analyzed using two and three harmonics to see what effect, if any, the additional terms would have on the value of the least square error. In each of these cases, the value used for $\lambda$ in the rod was that obtained from asymptotic theory.
RESULTS AND CONCLUSIONS

The analysis of the data for this work was identified by the following notation and parallels the notation used in the tables of original data found in Appendix D:

Case 1. One inch rod with gold wire near source.
Case 2. One inch rod with gold wire away from source.
Case 3. One inch rod with gold foil near source.
Case 4. One inch rod with gold foil away from source.
Case 5. Two inch rod with gold wire near source.
Case 6. Two inch rod with gold wire away from source.

The phrases "near source" and "away from source" refer to the position of the gold foil or wire with respect to the reactor core during the period of irradiation. Thus, "near source" signifies that the foil (or wire) was placed in the special graphite stringer in the position nearest the core, and "away from source" signifies that the foil (or wire) was placed in the special graphite stringer in the position farthest from the source (See Figure 23 in Appendix D).

The Tabulation of Results was further subdivided by the letters A, B, C, and D to indicate the method of analysis. These letters have the following meaning:

A. Data analyzed using one harmonic and the value of $\lambda_1$ obtained from asymptotic theory.
B. Data analyzed using one harmonic and the value of $\lambda_1$ obtained from diffusion theory.
C. Data analyzed using two harmonics and the value of
obtained from asymptotic theory.

D. Data analyzed using three harmonics and the value of \( \chi \), obtained from asymptotic theory.

For example, the results listed as Case 3B signify that the data recorded using the gold foil positioned in the stringer nearest the core were analyzed using one harmonic and the diffusion theory value for \( \chi \) in the rod.

Table 1 presents a tabulation of the results, identified by the preceding notation, obtained for the value of the effective rod radius, \( R_{\text{eff}} \), for both the one inch and the two inch diameter steel rod using the IBM 1620 computer program described in Appendix F. Figures 2 through 20 graphically illustrate the variation of the flux in the absorbing rod and moderator calculated by the least square analysis as compared to the experimental data.

For the analysis that utilized the value of \( \chi \) in the rod obtained from the solution of the transcendental equation \( \chi/\Sigma = \tanh \chi/\Sigma_s \), in only two instances did the value obtained for \( R_{\text{eff}} \) exceed the value of the physical rod radius. Both of these cases involved the one inch rod. In one instance, specifically Case 4, the value obtained for \( R_{\text{eff}} \) was not consistent with the values obtained in the other cases for the one inch rod. However, the validity of this data was questioned at the time it was recorded because the gold foil was noted to be out of position when it was removed from the special stringer. In both cases involving the two inch rod, the value
of $R_{\text{eff}}$ was less than the rod radius. Thus, one must conclude from these results that this method of analysis was not too satisfying from the standpoint of an effective rod radius. Although the calculated rod radius was greater than the physical radius of the rod in two instances, the majority of the results led to the conclusion that the absorbing rod was smaller in size than its actual measurement. Thus, the accuracy of the experimental data has left something to be desired.

In the analysis that used the diffusion theory value for $X$ in the rod, the value obtained for $R_{\text{eff}}$ in all cases was smaller than the rod radius. This result was not too surprising since diffusion theory is known (11) to be faulty in regions where $\Sigma_a$ is of the same order of magnitude as $\Sigma$. Hence, this method of calculating the effective rod radius was less satisfying than the first and should not be used to determine the effective rod radius.

When more than one harmonic was included in the analysis of the data, the general result was that the value of $R_{\text{eff}}$ increased and the least square error decreased. In one particular case utilizing the one inch rod, Case 1, the value of $R_{\text{eff}}$ calculated using one harmonic increased from 0.4604 inch to 0.5063 inch by using three harmonics while the least square error decreased from 541.4 to 352.1 respectively. The results of Case 2 present a more definite illustration of how the additional terms of the multi-harmonic analysis reduced the value of the least square error. For this case, the value of $R_{\text{eff}}$ calculated using one harmonic increased
from 0.5072 inch to 0.5488 inch for two harmonics and then decreased to 0.5138 inch for three harmonics. The value of the least square error in these three instances varied from 234.8 to 88.5 to 99.8 respectively.

The result that the inclusion of two or three harmonics improved the value of the least square error indicates that the foil or wire were too near the source and/or the end of the rod, and this resulted in the significance of the higher order harmonic terms. If the foil or wire had been located at a greater distance from the reactor core and if the rod had been longer, these terms would have been insignificant compared to the fundamental mode, one harmonic.

Case 2 results emphasize this fact. The wire used to record the data was located away from the core which means that it was ten inches farther from the core than was the wire that was located near the core, Case 1. For Case 2 the minimum least square error and the maximum value for $R_{eff}$ occurred using two harmonics to analyze the data. Thus, it appears that this little increase in distance was sufficient to reduce the effect of the third harmonic on the value of the flux.

The results for the multi-harmonic analysis of the two inch rod data were totally unexpected. Case 6 was selected for analysis since it presented the best prospect for producing an $R_{eff}$ on the order of the physical dimension of the rod judging from the results obtained for Case 1 and Case 2.
For two harmonics, the desired result was obtained when the value of the least square error decreased and $R_{\text{eff}}$ increased from the values obtained for one harmonic. However, when the three harmonic analysis was attempted, the value of both the least square error and $R_{\text{eff}}$ decreased. Thus, it appears that, as with Case 2, the wire was located far enough from the core to reduce the harmonic content of the flux to two harmonics, but the data were insufficiently accurate to produce the expected results.

It was also noted in the results of the multi-harmonic analysis that the sign on the term associated with the fundamental mode was negative in all cases, and that the second harmonic was the dominant term. Referring to Appendix G, it can be seen that the signs on the coefficients of the flux equations are exactly opposite what one’s intuition would suggest; i.e., one would expect the fundamental mode, the first harmonic, to be dominant and have positive coefficients, while the higher harmonics would be smaller in magnitude and have either positive or negative signs. Hence, it would appear that the original data were not as accurate as they could have been.

In the graphs of the original data, it was noticed from the beginning that unexpected peaks were evident in the moderating region. At first it was thought that these peaks were due to the location of the control rods used to bring the reactor to critical. But, in a later irradiation, these rods
were withdrawn completely and different ones were employed to cause the reactor to become critical and the peaks were still present. No explanation for these peaks was found when the data were recorded, and none is offered at this time.

Summarizing the results, it was seen that values for \( R_{\text{eff}} \) greater than the physical dimension of the rod were obtained in a few cases, and in these cases, the magnitude of the flux depression was very close to that obtained experimentally. For the cases in which \( R_{\text{eff}} \) was found to be less than the actual rod dimension, in one instance the data were known to be invalid, and in the others, the results were inconclusive since a multi-harmonic analysis of the data was not conducted.

Thus, it would appear that the concept of an effective rod radius was reasonable, but it will require much more investigation to produce graphs of the type that are needed to fully utilize this concept. Great care must be exercised when data for this type of experiment are recorded, and the location of the detecting material in relation to the reactor core is also important. To analyze the data for this type of investigation, computers of greater speed than the IBM 1620 would be very advantageous, especially for the multi-harmonic analysis. Examination of other materials and various rod sizes using the ideas embodied in this work would provide an excellent starting place for future experimentation.

Suggestions for Further Work

For the concept of an effective rod radius to be of use, graphs relating the dimensionless parameter $\Sigma_q R_l$ to the effective rod radius should be available. To construct graphs of this type and to determine the empirical representation for these graphs, various combinations of rod radius and absorber material should be investigated.

Since the primary problem in the determination of the effective rod radius is in the calculation of the coefficients in the flux equations, other representations for these terms could be examined. More rigorous boundary conditions, e.g., no return current at the outer boundary, might be examined to see what effect, if any, they would have on the value of the effective rod radius.

Because $P_1$ transport theory is just slightly more accurate than elementary diffusion theory, investigations considering higher order $P_n$ calculations should prove of interest. Some work has already been done in this area (13), but there is still much to be accomplished. This type of analysis is somewhat more difficult, but the improvement in the accuracy of the results should more than compensate for the extra labor involved.
ACKNOWLEDGMENT

The author wishes to express his sincere appreciation to the Kansas State University Engineering Experiment Station for its financial support and to the Atomic Energy Commission, who, through its fellowship program, made possible the opportunity for this study. Sincere gratitude is extended to Dr. Martin Grotenhuis who made available the facilities of the International School of Nuclear Science and Engineering for the recording of the data, and to the Association of Midwest Universities who provided the financial support for the work performed at the International School. Heartfelt thanks are extended to Dr. John O. Mingle of the Department of Nuclear Engineering for his guidance, encouragement, and help throughout this work, and to the other staff members for their particular contributions. Particular gratitude is extended to Dr. William R. Kimel, Head of the Department of Nuclear Engineering, for his advice and encouragement during the course of this work. Also thanks are given to Mr. Fred Prohammer who, through Dr. Kimel, suggested this problem.

APPENDICES
APPENDIX A

Derivation of the Boltzmann Transport Equation in Cylindrical Geometry

Following the notation of Weinberg and Wigner (16), the Boltzmann transport equation for the monoenergetic, steady state system is given as

$$\Omega \cdot \nabla f(r,\Omega) + f(r,\Omega) \Sigma(r) = S(\Omega) + \int d\Omega' f(r,\Omega) \Sigma_s(\Omega' \rightarrow \Omega)$$ \hspace{1cm} (A-1)

where

- $\Omega$ is the unit vector in the direction of the neutron motion,
- $f(r,\Omega) \, dr \, d\Omega$ is the angular flux; i.e., it is the number of neutrons in the volume element $dr$ around $r$ whose directions of motion lie in the solid angle $d\Omega$ about $\Omega$ times the speed $v$,
- $d\Omega$ is the differential solid angle,
- $\Sigma$ is the total cross section ($\Sigma = \Sigma_a + \Sigma_s$),
- $\Sigma_s(\Omega' \rightarrow \Omega)$ is the scattering cross section for changing $\Omega'$ into the direction $d\Omega$ about $\Omega$,
- $\Omega \cdot \nabla f$ is the directional derivative of $f$ in the direction $\Omega$; i.e., if the coordinate $s$ is extended in the direction $\Omega$, then

$$\Omega \cdot \nabla f = \frac{\partial f}{\partial s}.$$ \hspace{1cm} (A-2)
For a system with cylindrical symmetry and which is infinite in the z direction, the angular flux, $f$, depends on three variables. In the notation of Weinberg and Wigner (16), these variables are:

- $r$ — the distance from the axis of the cylinder, the z axis
- $\theta$ — the angle between $\Omega$ and z; and
- $\varphi$ — the angle between the projection of $\Omega$ on the x-y plane and the direction of $r$.

The geometry of the above described system is shown in Figure 21.

Note that when $d\varphi$ is small

$$\sin(\varphi + d\varphi) = \sin \varphi$$
$$\cos(\varphi + d\varphi) = \cos \varphi,$$
Thus,

\[-r\,d\varphi = ds \, \sin \theta \, \sin \varphi\]  \hspace{1cm} (A-3)

and

\[dr = ds \, \sin \theta \, \cos \varphi .\]  \hspace{1cm} (A-4)

Then

\[\frac{d\varphi}{ds} = -\frac{1}{r} \, \sin \theta \, \sin \varphi\]  \hspace{1cm} (A-5)

and

\[\frac{dr}{ds} = \sin \theta \, \cos \varphi .\]  \hspace{1cm} (A-6)

From Eq. (A-2) \( \Omega \cdot \text{grad} f = \frac{\partial f}{\partial s} \).

Since

\[f = f(r, \varphi)\]  \hspace{1cm} (A-7)

then

\[\frac{\partial f}{\partial s} = \frac{\partial f}{\partial r} \frac{dr}{ds} + \frac{\partial f}{\partial \varphi} \frac{d\varphi}{ds}\]  \hspace{1cm} (A-8)

so that

\[\frac{\partial f}{\partial s} = \frac{\partial f}{\partial r} \sin \theta \cos \varphi + \frac{\partial f}{\partial \varphi} [-\frac{1}{r} \sin \theta \sin \varphi],\]  \hspace{1cm} (A-9)

The substitution of Eq. (A-8) and Eq. (A-9) into Eq. (A-1) yields
\[
\sin \theta \cos \phi \frac{\partial f(r, \theta, \phi)}{\partial r} - \frac{1}{r} \sin \theta \sin \phi \frac{\partial f(r, \theta, \phi)}{\partial r} + \\
\Sigma(r) f(r, \theta, \phi) = S(r, \theta, \phi) + \\
\int d\Omega \Sigma_s(r, \cos \theta_0) f(r, \theta, \phi)
\]

which is the monoenergetic Boltzmann transport equation in cylindrical geometry with \( \varphi \) and \( \varphi \) symmetry.

To transform the Boltzmann equation to a more convenient form for computation, expand \( \Sigma_s(r, \cos \theta_0) \), \( f(r, \theta, \phi) \) and \( S(r, \theta, \phi) \) in spherical harmonics noting that \( \Sigma_s \) only depends on \( \theta_0 \), the angle between \( \Omega \) and \( \Omega' \).

Thus

\[
\Sigma_s(r, \cos \theta_0) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} \Sigma_{lm} P_{lm}(\cos \theta_0)
\]

\[
f(r, \theta, \phi) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} f_{lm} P_{lm}(\Omega)
\]

\[
S(r, \theta, \phi) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} S_{lm} P_{lm}(\Omega)
\]

where one form of \( P_{lm}(\Omega) \) is given by

\[
P_{lm}(\Omega) = \frac{e^{i m \phi} (-\sin \theta)^m}{(\ell! \ 2^{\ell} \ (\ell + m)!)} \sqrt{\frac{\ell + m}{2 \ell}} d^{\ell + m}(\cos^2 \theta - 1)^{\ell} \frac{d^{\ell + m}(\cos \theta)^{2 \ell + m}}{(d \cos \theta)^{2 \ell + m}}.
\]

In order that the spherical harmonics can be fully utilized, the following relations for this special use should be noted:

\[
P_{l,m}(\Omega) = (-1)^m P_{l,m}(\Omega)^* \]
where the * indicates the complex conjugate;
the orthogonality relation for Legendre polynomials:
\[
\int d\Omega \, P_{l,m}^{*}(\Omega) P_{l,m}(\Omega) = \frac{4\pi}{2l+1} \delta_{ll} \delta_{mm},
\] (A-16)
the addition theorem for Legendre polynomials:
\[
P_{l}(\cos \Theta) = \sum_{m=-l}^{l} P_{l,m}(\Omega) P_{l,m}(\Omega)^{*}
\] (A-17)
and finally, the recursion relations for the Legendre polynomials:
\[
\sin \theta e^{i\phi} = \frac{1}{2l+1} [2(2l-1)C_{l,m} P_{l-1,m+1}(\Omega) - 2(2l+3)A_{l,m} P_{l+1,m+1}(\Omega)]
\] (A-18)
\[
\sin \theta e^{i\phi} = \frac{1}{2l+1} [2(2l+3)B_{l,m} P_{l+1,m+1}(\Omega) - 2(2l+1)D_{l,m} P_{l-1,m+1}(\Omega)]
\] (A-19)
where
\[
A_{l,m} = \frac{[(l+m+1)(l+m+2)]^{1/2}}{2(2l+3)} \quad B_{l,m} = \frac{[(l-m+1)(l-m+2)]^{1/2}}{2(2l+3)}
\]
\[
C_{l,m} = \frac{[(l-m-1)(l-m)]^{1/2}}{2(2l+1)} \quad D_{l,m} = \frac{[(l+m-1)(l+m)]^{1/2}}{2(2l+1)}
\]
The substitution of Eqs. (A-11), (A-12), and (A-13) into Eq. (A-10) leads to
\[
\sin \theta \cos \phi \sum_{l=0}^{\infty} \sum_{m=-l}^{l} P_{l,m}(\Omega) \frac{\partial f_{l,m}(r)}{\partial r} - \frac{1}{i} \sin \theta \sin \phi \sum_{l=0}^{\infty} \sum_{m=-l}^{l} f_{l,m}(r) \frac{\partial P_{l,m}(\Omega)}{\partial \phi}
\]
\[
+ \sum_{l=0}^{\infty} \sum_{m=-l}^{l} f_{l,m}(r) P_{l,m}(\Omega) \Sigma(r) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} S_{l,m} P_{l,m}(\Omega)
\] (A-20)
\[
+ \int d\Omega \, f_{l,m}(\Omega) P_{l,m}(\Omega) \sum_{l=0}^{\infty} \sum_{m=-l}^{l} S_{l,m} P_{l,m}(\Omega) P_{l,m}(\Omega)^{*}
\]
Now multiply Eq. (A-20) by \( P_{l,m}(\Omega)^{*} d\Omega \) and integrate
over all $\Omega$. Examining each term, starting with the right-hand side, keeping in mind the orthogonality relation, it can be shown that:

$$\int \int f(r) P_m(\Omega) P_m(\Omega)^* d\Omega \sum_{l=0}^{\infty} \sum_{m=-l}^{l} S_{l,m}(\Omega) P_{l,m}(\Omega)^* d\Omega = [4\pi/(2l+1)] f(r) S_l$$

(A-21)

$$\int \sum_{l=0}^{\infty} \sum_{m=-l}^{l} S_{l,m}(\Omega) P_{l,m}(\Omega)^* d\Omega = [4\pi/(2l+1)] S_{l,m}$$

(A-22)

$$\int \sum_{l=0}^{\infty} \sum_{m=-l}^{l} f(r) P_{l,m}(\Omega) \sum_{r} (r) P_{l,m}(\Omega)^* d\Omega = [4\pi/(2l+1)] f(r) \sum_{r} (r)$$

(A-23)

For the first term on Eq. (A-20), write $\cos \phi$ in exponential form and then substitute the recursion relations Eqs. (A-18) and (A-19). Thus

$$\int \sin \theta \cos \phi \sum_{l=0}^{\infty} \sum_{m=-l}^{l} P_{l,m}(\Omega) P_{l,m}(\Omega)^* d\Omega \frac{\partial f_m(r)}{\partial r} =$$

$$\int \sin \theta [e^{i\phi} + e^{-i\phi}/2] \sum_{l=0}^{\infty} \sum_{m=-l}^{l} P_{l,m}(\Omega) P_{l,m}(\Omega)^* d\Omega \frac{\partial f_m(r)}{\partial r} =$$

$$\int \sum_{l=0}^{\infty} \sum_{m=-l}^{l} \frac{1}{2} \frac{\partial f_m(r)}{\partial r} d\Omega P_{l,m}(\Omega)^* \frac{1}{2l+1} \left[ 2(2l+1) C_{l,m} P_{l,m}(\Omega) - \right.$$

$$\left. 2(2l+3) A_{l,m} P_{l,m}(\Omega) + [2(2l+3) B_{l,m} P_{l,m}(\Omega) - 2(2l+1) D_{l,m} P_{l,m}(\Omega)] \right] =$$

$$\frac{4\pi}{2l+1} \left[ C_{l,m} \frac{\partial f_m(r)}{\partial r} - A_{l,m} \frac{\partial f_m(r)}{\partial r} + B_{l,m} \frac{\partial f_m(r)}{\partial r} - D_{l,m} \frac{\partial f_m(r)}{\partial r} \right].$$

(A-24)

The second term of Eq. (A-20) is handled in a like manner.
From Eq. (A-14) it is seen that
\[ \frac{\partial f_{lm}(\Omega)}{\partial \varphi} = \lambda m P_{lm}(\Omega). \]  
(A-25)

Thus
\[ \int \frac{1}{r} \sin \theta \sin \phi \sum_{l=0}^{\infty} \sum_{m, l} f_{lm}(r) P_{lm}(\Omega) \times d\Omega \frac{\partial f_{lm}(\Omega)}{\partial \varphi} = \]
\[ \int \frac{1}{r} \sin \theta \left[ e^{i\phi} - e^{-i\phi} / 2 \lambda \right] \sum_{l=0}^{\infty} \sum_{m, l} f_{lm}(r) P_{lm}(\Omega) \times d\Omega \lambda m P_{lm}(\Omega) = \]
\[ \int \sum_{l=0}^{\infty} \sum_{m, l} \frac{f_{lm}(r)}{r} P_{lm}(\Omega) \times d\Omega \frac{\lambda m}{2 \lambda (2 \lambda + 1)} \right] \left[ 2(2\lambda - 1) \right] C_{lm} P_{lm}(\Omega) - \]
\[ 2(2\lambda + 1) A_{lm} P_{lm}(\Omega) - \left. 2(2\lambda + 1) B_{lm} P_{lm}(\Omega) \right\} = \]
\[ \left[ 4\pi / (2\lambda + 1) \right] \left( C_{lm} f_{\lambda, m}^{(r)} \frac{m + 1}{r} - A_{lm} f_{\lambda, m}^{(r)} \frac{m + 1}{r} \right) \left( B_{lm} f_{\lambda, m}^{(r)} \frac{m - 1}{r} \right) + D_{lm} f_{\lambda, m}^{(r)} \frac{m - 1}{r}. \]

Regrouping Eqs. (A-21), (A-22), (A-24) and (A-25) in the proper order, the spherical harmonics form for the Boltzmann transport equation in cylindrical coordinates is obtained
\[ A_{lm} \left[ \frac{d}{dr} + \frac{m + 1}{r} \right] f_{\lambda, m}^{(r)} - B_{lm} \left[ \frac{d}{dr} - \frac{m - 1}{r} \right] f_{\lambda, m}^{(r)} = \]
\[ C_{lm} \left[ \frac{d}{dr} + \frac{m + 1}{r} \right] f_{\lambda, m}^{(r)} + D_{lm} \left[ \frac{d}{dr} - \frac{m - 1}{r} \right] f_{\lambda, m}^{(r)} + \]
\[ f_{\lambda, m}^{(r)} \Sigma(r) = S_{\lambda, m} + \left[ 4\pi / (2\lambda + 1) \right] f_{\lambda, m}^{(r)} s_{\lambda}. \]  
(A-27)
APPENDIX B

Derivation of the $P_1$ Transport Equation in Cylindrical Geometry

In order to derive the $P_1$ transport model for cylindrical geometry, the Boltzmann transport equation must be utilized. The solution of this equation can be found in many references (3, 5, 7, 11, 12, 16). The form of the Boltzmann equation that will be used in the derivation is that one found in Weinberg and Wigner (16) page 276 for a cylinder infinite in the $z$ direction and for monoenergetic neutrons. The equation has the form

$$A_{lm} \left[ \frac{\partial f}{\partial r} + \frac{m+1}{r} f_{l+1,m+1} \right] - B_{lm} \left[ \frac{\partial f}{\partial r} - \frac{m-1}{r} f_{l-1,m-1} \right] - C_{lm} \left[ \frac{\partial f}{\partial r} + \frac{m+1}{r} f_{l-1,m+1} \right] + D_{lm} \left[ \frac{\partial f}{\partial r} - \frac{m-1}{r} f_{l+1,m-1} \right] + \frac{4\pi}{2l+1} s_{l} f_{lm} - \Sigma f_{lm} + S_{lm} = 0 \quad (B-1)$$

where

$$A_{lm} = \frac{((l+m+2)(l+m+1))^{1/2}}{2(2l+3)} \quad B_{lm} = \frac{((l-m+1)(l-m+2))^{1/2}}{2(2l+3)}$$

$$C_{lm} = \frac{((l-m-1)(l-m))^{1/2}}{2(2l-1)} \quad D_{lm} = \frac{((l+m-1)(l+m))^{1/2}}{2(2l-1)}$$

For the $P_1$ approximation, $l = 0, 1$ while $-l \leq m \leq l$. The $f_{lm}$ equals zero for $l > 2$, and when $l = -1$. Because the medium of interest is assumed to be purely diffusing, the source term, $S_{lm}$, equals zero. In the $P_1$ approximation, scattering is assumed to be linearly anisotropic so that $s_0 \neq 0$ and $s_1 \neq 0$ while all other $s_{l} = 0$. 
Because of the cylindrical symmetry around the z-axis, the only $f_{l,m}$ of interest are those where $l + m =$ even. All other $f_{l,m}$ are neglected. (The equations for $l + m =$ even are independent of the $l + m =$ odd so that no part of a particular solution is omitted.)

Keeping the preceding facts in mind along with the property that, because of symmetry in the $\phi$ direction, $f_{l,-m} = (-1)^m f_{l,m}^*$, the following equations are obtained:

When $l = 0, \quad m = 0$

$$
\frac{\sqrt{2}}{3} \left[ \frac{\partial}{\partial r} + \frac{1}{r} \right] f_{11} + 4\pi S_{s} f_{oo} - \Sigma f_{oo} = 0 . \quad (B-2)
$$

When $l = 1, \quad m = 1$

$$
\frac{\sqrt{2}}{2} \frac{\partial f_{oo}}{\partial r} + \frac{4\pi S_{1} f_{11}}{3} - \Sigma f_{11} = 0 . \quad (B-3)
$$

Solving Eq. (B-3) for $f_{11}$

$$
f_{11} = \frac{\sqrt{2}}{2} \frac{\partial f_{oo}}{\partial r} \cdot \frac{1}{\Sigma - 4\pi S_{1}} \quad (B-4)
$$

and using the definition for $\Sigma_{tr}$ that is found in (16), Eq. (B-4) becomes

$$
f_{11} = \frac{\sqrt{2}}{2} \frac{\partial f_{oo}}{\partial r} \cdot \frac{1}{\Sigma_{tr}} . \quad (B-5)
$$

Substitution of Eq. (B-5) into Eq. (B-2) and assuming $\Sigma_{tr}$ is spatially independent leads to

$$
\frac{1}{3\Sigma_{tr}} \left[ \frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} \right] f_{oo} + (4\pi S_{s} - \Sigma) f_{oo} = 0 . \quad (B-6)
$$
Noting that \( 4\pi s_0 - \Sigma = -\Sigma_a \) and defining
\[
D \equiv \frac{1}{3\Sigma_{tr}}
\]  
(B-7)

for the \( P_1 \) approximation, Eq. (B-6) becomes
\[
D \nabla^2 f_{\infty} - \Sigma_a f_{\infty} = 0
\]  
(B-8)

where
\[
\phi_{\text{total}} = 4\pi f_{\infty}
\]  
(B-9)

and \( \nabla^2 \) is the well known Laplacian operator.

Thus, the \( P_1 \) transport equation is identical in form with the thermal diffusion equation except for the definition of \( D \), the diffusion coefficient.

The net current in the \( r \) direction can also be obtained using the preceding method and equations.

When \( \lambda = 1, \mu = -1 \), Eq. (B-1) becomes
\[
-\frac{\sqrt{2}}{2} \frac{\partial f_{\infty}}{\partial r} + \frac{4\pi s_1}{3} f_{i,-1} - \Sigma f_{i,-1} = 0.
\]  
(B-10)

Now subtract Eq. (B-10) from Eq. (B-3) and obtain
\[
\sqrt{2} \frac{\partial f_{\infty}}{\partial r} + \frac{4\pi s_1}{3} [f_{i,-1} - f_{i,-1}] - \Sigma [f_{i,1} - f_{i,-1}] = 0.
\]  
(B-11)

Using the previous definition of \( \Sigma_{tr} \), Eq. (B-11) becomes
\[
\sqrt{2} \frac{\partial f_{\infty}}{\partial r} - \Sigma_{tr} [f_{i,1} - f_{i,-1}] = 0.
\]  
(B-12)

Now use Eq. (B-7) to define \( D \) and rearrange Eq. (B-12) into the form
\[
J(r) = -D \nabla f_{\infty} = \frac{2^{-\frac{1}{2}}}{3} [f_{i,-1} - f_{i,1}]
\]  
(B-13)
where \( \nabla \) represents the gradient operator in cylindrical coordinates with no \( \phi \) or \( z \) dependence.
APPENDIX C

The Orthogonality Condition for $U_0(\alpha r)$

$U_0(\alpha r)$ is a solution of Bessel's equation

$$\frac{1}{r} \frac{d}{dr} \left( r \frac{d \omega}{dr} \right) + \alpha^2 \omega = 0 \quad (C-1)$$

where the boundary condition

$$\omega(b) = 0 \quad (C-2)$$

has been applied. For this case

$$\omega(r) = U_0(\alpha r) \equiv J_0(\alpha b) Y_0(\alpha r) - Y_0(\alpha r) J_0(\alpha b) \quad (C-3)$$

Let $U_0(\alpha r)$ be a solution of Eq. (C-1) and let

$U_0(\beta r)$ be a solution of

$$\frac{1}{r} \frac{d}{dr} \left( r \frac{d \nu}{dr} \right) + \beta^2 \nu = 0 \quad (C-4)$$

where $\nu(r) = U_0(\beta r)$. Multiply Eq. (C-1) by $\nu$ and Eq. (C-4) by $\omega$ and subtract Eq. (C-4) from Eq. (C-1). Thus

$$(\beta^2 - \alpha^2) r \nu \omega = \nu \frac{d}{dr} \left( r \frac{d \omega}{dr} \right) - \omega \frac{d}{dr} \left( r \frac{d \nu}{dr} \right)$$

$$= \frac{d}{dr} [r (\nu \frac{d \omega}{dr} - \omega \frac{d \nu}{dr})] \quad (C-5)$$

Now multiply Eq. (C-5) by rdr and integrate over $(a, b)$, the interval of interest.
Thus

$$(\beta^2 - \alpha^2) \int_a^b r \nu \omega \, dr = \int_a^b \frac{d}{dr} \left[ r \left( \frac{d \omega}{dr} - \omega \frac{d \nu}{dr} \right) \right] \, dr$$

$$= \left[ r \left( \frac{d \omega}{dr} - \omega \frac{d \nu}{dr} \right) \right]_a^b.$$  \hspace{1cm} (C-6)

From the preceding definitions of $\nu$ and $\omega$ it is easily seen that both $\nu$ and $\omega$ are zero when evaluated at the upper limit. Thus, evaluating Eq. (C-6) at the lower limit

$$\int_a^b r \nu \omega \, dr =$$

$$-\alpha \left\{ U_0(\beta a) \left( -\alpha U_0'(\alpha a) - U_0(\alpha a) [\beta U_0'(\beta a)] \right) \right\}$$

where

$$\frac{d \omega}{dr} = -\alpha [J_1(\alpha r) Y_0(\beta a) - Y_1(\alpha r) J_0(\beta a)]$$

$$= -\alpha U_0'(\alpha r) = -\alpha U_1(\alpha r)$$ \hspace{1cm} (C-8)

and

$$\frac{d \nu}{dr} = -\beta [J_1(\beta r) Y_0(\beta b) - Y_1(\beta r) J_0(\beta b)]$$

$$= -\beta U_0'(\beta r) = -\beta U_1(\beta r).$$ \hspace{1cm} (C-9)

Eq. (C-7) can be rearranged into the form

$$\int_a^b r \nu \omega \, dr = \kappa_0 \left[ \alpha U_0'(\alpha a) + \kappa_1 U_0(\alpha a) \right]$$

$$= \kappa_0 \left[ \alpha U_0'(\alpha a) + \kappa_1 \frac{\beta U_0'(\beta a) U_0(\beta a)}{U_0'(\beta a)} \right]$$

where

$$\kappa_0 = \alpha U_0(\beta a)$$ \hspace{1cm} (C-11)

$$\kappa_1 = -\beta U_0'(\beta a) / U_0(\beta a).$$ \hspace{1cm} (C-12)
Now, if \( \alpha \) and \( \beta \) are positive roots of the equation
\[
\alpha U_0(\alpha r) + \beta_1 U_0(\alpha r) = 0
\]  
then
\[
\int_{a}^{b} rU_0(\beta r)U_0(\alpha r) \, dr = 0
\]
which is the orthogonality condition for \( U_0(\alpha r) \).

In order to evaluate the integral
\[
\int_{a}^{b} rU_0^2(\alpha r) \, dr
\]
take Eq. (C-1) and multiply it by \( 2r \frac{d\omega}{dr} \):
\[
2r \frac{d\omega}{dr} \cdot \frac{d}{dr} (r \frac{d\omega}{dr}) + 2r \frac{d\omega}{dr} r \alpha^2 \omega = 0.
\]
Rearranging the terms of Eq. (C-15) yields
\[
\frac{d}{dr} (r \frac{d\omega}{dr})^2 + \alpha^2 r^2 \frac{d}{dr} (\omega^2) = 0.
\]
Now multiply Eq. (C-16) by \( dr \) and integrate over \((a,b)\), the region of orthogonality:
\[
\int_{a}^{b} \frac{d}{dr} (r \frac{d\omega}{dr})^2 \, dr + \alpha^2 \int_{a}^{b} r^2 \frac{d}{dr} (\omega^2) \, dr = 0.
\]
Integrating the second term by parts and the straightforward integration of the first term yields
\[
[(r \frac{d\omega}{dr})^2]_{a}^{b} + \alpha^2 [r^2 \omega^2]_{a}^{b} - 2 \alpha^2 \int_{a}^{b} r \omega^2 \, dr = 0.
\]
Rearranging Eq. (C-18) and evaluating the expressions for \( \omega^2 \) and \( (\frac{d\omega}{dr})^2 \) at the limits yields the following
equation:
\[ 2 \alpha^2 \int_{a}^{b} r U_{\alpha}^2(\alpha r) \, dr = \left( \frac{b^2}{\alpha^2} U_{\alpha}^2(\alpha b) - \frac{a^2 \alpha^2}{\alpha^2} U_{\alpha}^2(\alpha a) - \frac{\alpha^2}{\alpha^2} U_{\alpha}^2(\alpha a) \right). \]  
\[ \text{(C-19)} \]

From Murray (12), the Wronskian relation is given as
\[ J_{\alpha}(X) Y_{1}(X) - J_{1}(X) Y_{\alpha}(X) = - \frac{2}{\pi X}. \]  
\[ \text{(C-20)} \]

Using Eq. (C-8) as a definition for \( U_{\alpha}(\alpha b) \), it is easily seen that
\[ U_{\alpha}(\alpha b) = \frac{2}{\alpha \pi b} \]  
\[ \text{(C-21)} \]

and by applying the definition for \( U_{\alpha}(\alpha a) \) as given in Eq. (C-13), Eq. (C-19) becomes
\[ \int_{a}^{b} r U_{\alpha}^2(\alpha r) \, dr = \frac{1}{2 \alpha^2} \left\{ \frac{4}{\pi^2} - \alpha^2 \alpha^2 \left[ \frac{\frac{4}{\pi^2}}{\alpha^2} U_{\alpha}^2(\alpha a) + U_{\alpha}^2(\alpha a) \right] \right\} \]  
\[ = \frac{1}{2 \alpha^2} \left\{ \frac{4}{\pi^2} - \alpha^2 \alpha^2 U_{\alpha}^2(\alpha a) \left[ \frac{\frac{4}{\pi^2}}{\alpha^2} + 1 \right] \right\}. \]  
\[ \text{(C-22)} \]

Another integral that must be considered is
\[ \int_{a}^{b} r U_{\alpha}(\alpha r) \, dr. \]  
\[ \text{(C-23)} \]

Writing the equivalent expression for \( U_{\alpha}(\alpha r) \), the integral becomes
\[ \int_{a}^{b} r U_{\alpha}(\alpha r) \, dr = \int_{a}^{b} r \left[ J_{\alpha}(\alpha r) Y_{\alpha}(\alpha b) - Y_{\alpha}(\alpha r) J_{\alpha}(\alpha b) \right] \, dr. \]  
\[ \text{(C-24)} \]

Performing the indicated integration:
\[
\int_a^b r U_\alpha(\alpha r) \, dr = \left[ \frac{r}{\alpha} \left[ U_1(\alpha r) Y_0(\alpha b) - Y_1(\alpha r) U_0(\alpha b) \right] \right]_a^b
\]

\[= \left[ \frac{r}{\alpha} U_1(\alpha r) \right]_a^b \]

\[= \frac{b}{\alpha} U_1(\alpha b) - \frac{a}{\alpha} U_1(\alpha a), \tag{C-25}\]

Substituting the value for \( U_1(\alpha b) \) from Eq. (C-21) and the value for \( U_1(\alpha a) \) from Eq. (C-13), Eq. (C-25) becomes

\[
\int_a^b r U_\alpha(\alpha r) \, dr = \frac{2}{\pi \alpha^2} + \frac{a}{\alpha^2} \, k_1 U_\alpha(\alpha a), \tag{C-26}\]

Further discussion of the properties of this function can be found in Carslaw and Jaeger (2).
APPENDIX D

Experimental Facilities

The experimental facilities used to compile the preliminary data employed in this work were the Argonaut Training Reactor of the International School of Nuclear Science and Engineering located at Argonne National Laboratory. The use of these facilities was made possible through the courtesy and cooperation of the International School of Nuclear Science and Engineering and the Association of Midwestern Universities. It is noted that the experimental phase of this work was completed before the Kansas State University TRIGA MARK II Reactor went critical.

A complete description of the Argonaut reactor can be found in references (10, 15). The following will be a short account of the actual facilities used.

The foils were irradiated in the external graphite thermal column. The thermal column is an extension of the reactor reflector graphite, and it is four feet by five feet in cross section by six feet long. It is composed of assorted lengths of machined reactor grade graphite four inches in cross section. A total of fifteen removable horizontal stringers are available for access in the direction of the core. The J-10 stringer was the one in which the experimental measurements were made. It is located on the vertical and horizontal center line of the core.
The core of the Argonaut reactor system is annular in design, and it is reflected internally and externally with graphite. The fuel elements are heterogeneous and consist of BORAX-type fuel plates (15) in rectangular assemblies three by six inches. Light water serves as the moderator in and surrounding each fuel box while graphite moderator pieces separate the individual fuel boxes.

Because of the annular design of the core, the core can be loaded with fuel in two different configurations for power runs: a one slab loading or a two slab loading. The one slab loading consists of six fuel boxes placed in the annulus separated only by the graphite moderator pieces. When a two slab loading is required, an identical configuration of fuel elements is located diametrically opposite the initial loading.

The critical loading of the two slab system is approximately four kilograms of U-235 at 20% enrichment. With this loading the reactor will normally operate in the range of one to one hundred watts. The reactor can operate continuously at one kilowatt and is capable of operation at a maximum thermal power of ten kilowatts.

For this particular work, a one slab loading was used, and the fuel elements were placed in position nearest the thermal column; as shown in Figure 22.
FIG. 22 ARGONAUT CORE AND THERMAL COLUMN SKETCH.
Experimental Procedure

The data compiled for this work were taken by the method outlined in the main body, and the pertinent details will be presented here.

The absorber rods were steel measuring one inch and two inches in diameter. The gold wire was used to record data for both the one inch and the two inch rod while the gold foil was used only in conjunction with the one inch rod. Both rods were cut into three sections; the center section was ten inches long; the forward section, the section nearest the core, was six inches long; and the aft section was eight inches long (see figure 23).

The center section had a slot, 1/32 inch wide by 9/32 inch deep, located on the center line of the rod cut into each end. Into each slot, one gold wire or one gold foil was placed depending on the phase of the experiment. The wire or foil was of such a length that it extended from the edge of the special graphite stringer to approximately one inch beyond the edge of the rod when the rod was in place in the stringer. The special stringer, with a graphite rod in the position of the steel rod not being used, was then placed in position for the irradiation. The wire or foil was irradiated for a period of one hour while the reactor was operated at a power level of 100 watts.

The reactor was shut down at the conclusion of the irradiation period by a "scram" procedure, and the time at
FIG. 23 SPECIAL STRINGER FOR IRRADIATING GOLD FOIL AND GOLD WIRE.
which this occurred was recorded. Following the shut down, the special stringer was removed from the thermal column, and allowed to cool off. The wires, or foils, were then removed from the stringer and transported to the counting facility which was located at some distance from the irradiation facility.

The wire was counted as described previously. The counting tube was an end window Geiger-Mueller type. As the wire was advanced under the G-M tube, it was always moved a sufficient distance to prevent counting a portion of the same section of the wire twice. At large distances from the center of the rod, the wire was advanced in steps of one-eighth inch. In the immediate vicinity of the rod, the step was reduced to one-sixteenth inch, the diameter of the hole in the wire guide. This increment was maintained until the wire was advanced past the region where the rod had been positioned. At each position where a count was taken, the time when the counting began was recorded.

The foil counting procedure was that one described previously. The foil was taped to a piece of graph paper having ten divisions per one-half inch. The foil was then cut into narrow strips approximately 0.050 inches wide. These small strips of foil were then placed on a special plancet and counted using a gas flow proportional counter. At large dis-
tances from the rod, the small strips were counted every quarter inch. In the proximity of the rod, each individual strip was counted. At each position where a count was taken, the time when the counting period began was recorded.

Counting Facilities

The facility used to count the irradiated gold wire was one that had been previously constructed by the International Institute specifically designed to count irradiated wires. The apparatus consisted of an Argonne scaler, a Nuclear Chicago Model 3031B Geiger-Mueller counting chamber, and a wire guide.

The wire guide and counting chamber were so constructed that only a small section of the wire could be "seen" by the end window G-M tube. The portion of the wire guide below the G-M tube was constructed of lead to prevent radiation from the wire from being scattered into the counting region of the tube; see Figure 21.

The equipment had been checked by a member of the Laboratory staff, and it was found to operate best at a voltage of 1400 volts with a discriminator setting of 175. When a Chi-square test was run using a standard beta ray source, the equipment was found to be operating with a high confidence probability, 80%. 
To count the gold foil, a gas flow proportional counter and a scaler were used. The scaler was the Argonne type, and the counting chamber was a lead shielded "pig" type into which a continuous flow of P-10 gas, a mixture of 10% methane and 90% argon, was passed to maintain the background radiation level as low as possible.

A member of the Laboratory staff had checked this apparatus and found that it operated best at a voltage of 3150 volts with a discriminator setting of 50. When a Chi-square test was run using a standard beta ray source, this equipment was found to be operating with a high confidence probability, 80%.

Treatment of Raw Data

The data for each gold wire and gold foil were corrected for the background counts, the decay of the sample that occurred previous to being counted, and the dead time of the counting equipment. These corrected data are listed in Tables 2 through 7 in the form of counts per minute. The deviation reported is the standard deviation of a single observation. Each sample was counted for a sufficient length of time to reduce the standard error to approximately 1%. An IBM 1620 computer program was used to make the corrections, and the program is described in Appendix E.
The data points near the outer boundary of the graphite stringer were rejected for the determination of the effective rod radius because they were not consistent with the remainder of the data.

Description of Tables

The tables of the original data, Tables 2 through 7, are identified by the following notation:

Case 1. One inch rod with gold wire near source.
Case 2. One inch rod with gold wire away from source.
Case 3. One inch rod with gold foil near source.
Case 4. One inch rod with gold foil away from source.
Case 5. Two inch rod with gold wire near source.
Case 6. Two inch rod with gold wire away from source.

The phrases "near source" and "away from source" refer to the location of the gold foil or wire with respect to the reactor core during the period of irradiation. Thus, near source means that the foil (or wire) was placed in the special graphite stringer in the position nearest the core. Away from source means that the foil (or wire) was placed in the special graphite stringer in the position farthest from the core.

The data in these tables have been corrected for the background counts, the decay of the sample that occurred
previous to being counted, and the dead time of the counting equipment. The deviation that is reported is the standard deviation of a single observation.

APPENDIX E

IBM 1620 Program to Correct Raw Data

This computer program was written to correct the raw counted data for background counts, the counter dead time, and the decay of the sample previous to being counted. The program was written in FORTRAN I, and it utilized the automatic floating point subroutines EXP and SQRT. The logic diagram and the object program are given in this section.

Input for this program consisted of the experimental value of the counts, the length of time, in minutes, that elapsed to record the counts, the value of the exponent for the decay correction, and the number of the sample being corrected. A base value was also included to permit the counts to be based on any desired length of time. The data for each point was punched on a single card according to the specified format statement and read into the computer after the object program and the subroutines had been stored.

The output can be in either punched or typed form depending on the setting of sense switch two. One output card was punched for each input card that was read. The output consisted of the corrected count rate, the number of the sample that was corrected, and the standard deviation of the count rate.
The operating time for this program was approximately one second to correct one data point.

To correct the raw data counts recorded using the gold foil, a separate program was written. This program accounted for the variation in the weights of the individual foils.

The input for this program was identical to that of the program that processed the wire data except the weight of the foil, in milligrams, was included. The data for each point are punched on a single card according to the specified format statement and read into the computer after the object program and the subroutines had been stored.

The output for this program was identical to that of the wire data processing program. The operating time for this program was approximately one second per data point.

APPENDIX F

Description and Explanation of the IBM 1620 Computer Program to Determine the Effective Rod Radius From a Set of Experimental Data

To determine the effective rod radius from the experimental data, it is necessary to select a method to calculate the coefficients in the flux equations

\[ \phi_i^R(r) = \sum_{j} A_{ij} \frac{\Gamma_{ij}}{\beta_j r_i} \]  (F-1)

and

\[ \phi_i^M(r) = \sum_{j} \left[ B_{ij} J_0(\alpha_j r_i) + Y_0(\alpha_j r_i) C_j \right] \]  (F-2)

where \( j \) is summed over the number of harmonics included in the analysis of the data, and \( i \) is the position at which the flux was measured. To calculate these coefficients, the method of weighted least squares is used.

A weighting factor in a least squares problem may be utilized in two ways: one, by requiring that the sum of the weighted residuals squared be a minimum; or two, by requiring that the residual between the calculated value at any point should lie within the statistical standard deviation of the experimental measurement. A weighting factor of unity satisfies the first method best. Scarborough (14) points out that the residuals squared are best weighted with the reciprocal of the standard deviation, \( 1/\sigma^{-2} \), if the second method is to
be satisfied.

Recall from the theory section that the constants $\alpha_j$ and $\beta_j$ are related by the equations

$$\beta_j^2 = \lambda_1^2 - \lambda_2^2 - \alpha_j^2$$ \hspace{1cm} (F-3)

$$\frac{I_o(\beta_j R_1)}{D_j \beta_j I_1(\beta_j R_1)} = -\frac{J_o(\alpha_j R_1) - T Y_o(\alpha_j R_1)}{D_2 \alpha_j (J_1(\alpha_j R_1) - T Y_1(\alpha_j R_1))}$$ \hspace{1cm} (F-4)

where $T = J_o(\alpha_j R_1)/Y_o(\alpha_j R_1)$ and $\lambda_1^2$ and $\lambda_2^2$ are constants of the rod and the moderator.

Thus, it is evident that for a given value of $R_1$ and $R_2$, the simultaneous solution of Eqs. (F-3) and (F-4) will yield a proper value for $\alpha_j$ and $\beta_j$. In order to begin the calculation with a reasonable value for $\alpha_j$ and $\beta_j$, an initial value for $\alpha_j$ is estimated by using the boundary condition that the flux goes to zero at the outer boundary, $R_2$.

Once the value of $\alpha_j$ and $\beta_j$ for a given $R_1$ is determined, the unknown coefficients in the flux equations are calculated by the method of least squares. The equation that must be solved is

$$\mathbb{E} = \sum \tilde{W}_c \left( \phi_c - \sum M_{ji} \right)^2$$ \hspace{1cm} (F-5)

where

$$M_{ji} = A_j I_o(\beta_j r_i) \hspace{2cm} 0 \leq r \leq R_1$$ \hspace{1cm} (F-6)

$$M_{ji} = B_j J_o(\alpha_j r_i) + C_j Y_o(\alpha_j r_i) \hspace{1cm} R_1 \leq r \leq R_2$$ \hspace{1cm} (F-7)
In order that this method might fully be utilized, it is necessary to express all the unknown coefficients in terms of one of their number. The coefficient $B_j$ is selected as the main unknown. Using the boundary condition that

$$
\phi^m(R2) = 0 \quad (F-8)
$$

$$
\phi^m(R1) = \phi^a(R1) \quad (F-9)
$$

the expressions for $C_j$ and $A_j$ are obtained:

$$
C_j = -B_j \frac{J_0(\alpha_j R2)}{Y_0(\alpha_j R2)} \quad (F-10)
$$

$$
A_j = \frac{B_j [J_0(\alpha_j R1) - T_j Y_0(\alpha_j R1)]}{I_0(\beta_j R1)} \quad (F-11)
$$

where $T_j = \frac{J_0(\alpha_j R2)}{Y_0(\alpha_j R2)}$.

Operating on Eq. (F-5) in the usual manner, the equation for the determination of the unknown coefficients is obtained:

$$
\sum_j B_j \sum_k \omega_i M_{jik} M_{kii} = \sum_k \omega_i \phi M_{kii} \quad (F-12)
$$

where

$$
M_{kii} = \left\{ \left[ J_0(\alpha_k R1) - T_k Y_0(\alpha_k R1) \right] / I_0(\beta_k R1) \right\} I_0(\beta_k r_i) \quad 0 \leq r \leq R1 \quad (F-13)
$$

$$
M_{kii} = J_0(\alpha_k r_i) - T_k Y_0(\alpha_k r_i) \quad R1 < r \leq R2 \quad (F-14)
$$

and as before

$$
T_k = \frac{J_0(\alpha_k R2)}{Y_0(\alpha_k R2)}. \quad (F-15)
$$
After the coefficients $A_j$, $B_j$, and $C_j$ are obtained, the least squared error is calculated using Eq. (F-5). This value is stored, $R_l$ is incremented, and the procedure is repeated, starting with the determination of $\alpha_j$ and $\beta_j$.

The value of $R_l$ is incremented twice from the original value, and the least squared error at each of these values of $R_l$ is subtracted in the manner of forward differences. These differences, along with the average value of the radii used to obtain the errors are then used to determine a straight line that intersects the axis of the graph, $\Delta$ Error vs. $R_l$, at the position of an estimate of the minimum on the error curve. (See Figure 25)

Using this value of $R_l$ as the best estimate of the minimum of the error curve, the least squared error for this position is calculated and stored. $R_l$ is incremented, once in the direction of increasing $R_l$ and once in the direction of decreasing $R_l$, and the least squared error at each of these positions is calculated, stored, and used to determine a $\Delta$ Error and a new $R_l$ as before.

After the error is calculated with this second estimate of the minimum of the error curve, it is compared to the error calculated with the first estimate of the minimum. If these errors are close together and the absolute value of their difference is less than or equal to a given criterion, the
Fig. 25 Graphical Representation of How Iteration Procedure Progresses.
calculation is complete. Then the values of the unknown coefficients, $\alpha_j$ and $\beta_j$, the value of the effective rod radius, and the flux plot that results in the minimum least squared error is punched.

If the error criterion is not satisfied, the two radii that estimate the minimum error are compared. If they are close together and the absolute value of their difference is less than or equal to a preset value, the calculation is complete, and the required information is punched. If the radii accuracy criterion is not satisfied, the errors associated with these radii are compared to determine which is the smaller. The smallest error and the associated radius is stored, and the iteration to determine the minimum error proceeds.

The amount of output obtained during the iterations, and the type of analysis to be employed during the calculations can be controlled by the proper setting of the four sense switches. If sense switch 1 is ON while the input data is being read into the computer, the initial values of the count rate, the position, with respect to the center of the rod, at which the count was recorded, and the weighting factors are punched. If switch 1 is OFF, all of this output is omitted. When switch 1 is ON while the iterations are in progress,
the intermediate values of $\alpha_j$ and $\beta_j$ from the solution of Eq. (F-4) are punched. This output is omitted if switch 1 is turned OFF during the iterations.

When sense switch 2 is turned ON during the iterations, the value of the least squared error and the radius at which it was calculated is punched. If switch 2 is OFF, this output is eliminated. Turning switch 2 ON as the input data is being read causes the transcendental equation for $X$ in the rod to be solved. If the switch is OFF as the data is read, the diffusion theory value for $X$ is calculated and used for the determination of the effective rod radius.

Turning sense switch 3 ON will cause an exit from the program during the iterative calculation for $\alpha_j$ and $\beta_j$ or following the punching of the least squared error and Rl. Sense switch 2 must be turned ON to exit following the punching of the error and Rl. When this exit occurs, all of the output that results when the calculation ends in a normal fashion is punched. Care must be exercised when this exit is chosen. A minimum of eight iterations must have occurred before this type of exit is attempted. If sense switch 3 is OFF, the exit is omitted, and the end of calculation type output is eliminated.

The internal subroutine CRAM also operates on sense switch 3. If switch 3 is ON and the calculation of the unknown flux coefficients is in process, the value of the matrix elements (Eq. (F-12)) is typed before the matrix is solved. When switch 3 is OFF, this output is omitted.
Because of the nature of the operations connected with the use of sense switch 3, it must be used with caution.

If the program is compiled with the trace instructions included, sense switch 4 controls typed output. The compilation of the trace instructions and the use of sense switch 4 are primarily for the "debugging" of new programs. When switch 4 is ON, the values to the left of all equal signs are typed out. This type of output greatly slows the operation of the computer. So, unless a program is troublesome, sense switch 4 is normally left turned OFF.

ABSTRACT

The usual method of treating the problem of self-absorption in an absorbing media is by use of an effective cross section which, when multiplied by the average neutron flux within the absorber, yields the proper magnitude of the flux depression. In this work, the problem of self-absorption was investigated from the stand point of an effective rod radius. This approach was developed by use of the $P_1$ transport model.

The mathematical theory of the $P_1$ transport model in cylindrical geometry for a two region, absorbing and moderating, system was developed, and analytical expressions for the neutron flux in each region were given. Two different source conditions were considered in the development, and the coefficients in the flux equations were presented.

The flux depression in the rod as the result of self-absorption was approached from the stand point of an effective rod radius instead of an effective cross section as is the usual case. Several sets of data for a one inch and a two inch diameter steel rod were analyzed by an IBM 1620 computer program that varied the radius of the absorbing rod in order to obtain the best neutron absorption as calculated using the $P_1$ transport model.

The data were analyzed by fitting the correct expression for the flux in each region while requiring that the weighted sum of the square of the residuals should be a minimum. All
of the data were analyzed using one harmonic and the value obtained from the asymptotic theory expression for $\mathcal{K}$, the inverse diffusion length, in the rod. Selected sets of data were analyzed using two and three harmonics. A comparison was made between $P_1$ transport theory and diffusion theory by analyzing the data using one harmonic and the diffusion theory value for $\mathcal{K}$ in the rod.

The results obtained for the effective rod radius indicated that this approach to the problem of the self-absorption effect was feasible. However, the amount of data used in this work were insufficient to fully verify the approach, and considerably more experimental data would be required to adequately support the concept of an effective rod radius.
